Foreword

Planning for future urban water supply needs in California entails a wide range of efforts by local, State, and federal water agencies and other interested parties. Analysis of past water use trends is important to the effectiveness of this effort and the reliability of forecasts of water needs. The Department of Water Resources has surveyed retail water agencies and analyzed their water production data for over 35 years and has made the results available since 1968 through the Bulletin 166 series.

Bulletin 166-4 is a compilation of monthly urban water production data from nearly 300 retail water purveyors for the decade ending 1990. The data come from service areas in all 10 hydrologic regions (major water planning subdivisions) of the State. Socioeconomic and natural phenomena, notably climate, population growth, and pricing, which have influenced water use trends in the 1980s are discussed. The text also provides an analysis of urban water use by hydrologic regions and the major sectors (residential, commercial, industrial, and governmental). The urban water demands cited in the recent *California Water Plan Update*, Bulletin 160-93, are largely based on Bulletin 166-4 data.

The intent of Bulletin 166-4 is to provide the water community with information on the urban water use data that can be employed in statewide and regional water planning decisions. Estimates of per capita water use can indicate changes in water use patterns for a community, a region, an industry, or the State.

Bulletin 166-4 introduces the Water Savings Simulation Program, a model for urban water use forecasting developed by the Department with the University of California, Los Angeles. The Department hopes that this model will be an effective tool for planning and calculating future urban water demands.

Raymond E. Barsch
Executive Officer

The California Water Commission serves as a policy advisory body to the Director of Water Resources on all California water resources matters. The nine-member citizen commission provides a water resources forum for the people of the State, acts as a liaison between the legislative and executive branches of State Government, and coordinates federal, state, and local water resources efforts.

Department of Water Resources

Mission

To manage the water resources of California, in cooperation with other agencies, to benefit the State's people and protect, restore, and enhance the natural and human environments.

Major responsibilities of the Department are to:

- ◆ **Prepare and update the California Water Plan** to guide development and management of the State's water resources.
- ◆ **Plan, design, construct, operate, and maintain the State Water Resources Development System** to supply good water quality for municipal, industrial, agricultural, and recreational uses for fish and wildlife protection and enhancement.
- ◆ **Protect and restore the Sacramento-San Joaquin Delta** by controlling salinity and providing water supplies for Delta water users; planning long-term solutions for environmental and water use problems facing the Delta; and administering levee maintenance reimbursements and special flood control projects.
- ◆ **Regulate dams, provide flood protection, and assist in emergency management to safeguard life and property** by supervising design, construction, operation, and maintenance of more than 1,200 jurisdictional dams; encouraging preventive floodplain management practices; maintaining and operating Sacramento Valley flood control facilities; cooperating in flood control planning and facility development; and providing flood advisory information.
- ◆ **Educate the public** about the importance of water and its proper use and collect, analyze, and distribute water-related information to the general public and to the scientific, technical, educational, and water management communities.
- ◆ **Serve local water needs** by providing technical assistance, cooperating with local agencies on water resources investigations, supporting watershed and river restoration programs, encouraging water conservation, exploring conjunctive use of ground and surface water, facilitating voluntary water transfers, and, when needed, operating a State drought water bank.

Authorization

The California Water Code and Constitution require that the water resources of the State be put to beneficial uses to the fullest extent possible, and that waste, unreasonable use, or unreasonable methods of water use be prevented. The law charges the Department of Water Resources and other State agencies with the responsibility to ensure protection of the State's water resources for the benefit of present and future generations. The Department operates under a mission statement that dedicates its efforts toward fulfillment of this obligation. This report helps the Department meet the first, fifth, and sixth goals of its mission. Collecting and reporting statewide water information is necessary to forecast future water demands and plan to meet future local and statewide needs.

In the 1940s, the Division of Water Resources under the Department of Public Works (predecessor to the Department of Water Resources) began compiling water use data. In 1959, Section 226 was added to the Water Code, enabling the Department to collect records on diversion and use of water, and conduct investigations on actual water use for various purposes. Further, Section 232 directed the Department to conduct investigations and prepare findings on current uses of water within each watershed. Water data collection is a cooperative effort among federal and State agencies and water purveyors and users throughout the State. Data and analyses are made available to those with an interest or a need for the information. The Department publishes its findings in the reports discussed below.

DWR Water Use Reports

Bulletin 160 Series

In 1957, the Department published the *California Water Plan* (Bulletin 3), a report detailing current water use and supply along with major aspects of water planning and de-

velopment. Since 1966, the Plan has been updated six times under the Bulletin 160 series most recently as Bulletin 160-93, *California Water Plan Update*. Each update summarized the Department's findings on statewide developed water supply and uses including projections for up to 30 years into the future.

For the first time, Bulletin 160-93 presented *average* water year and *drought* year water demand and supply scenarios through the year 2020. Also, Bulletin 160-93 gave full standing to environmental water use as a major category along with urban and agricultural water use. Table 1-1, taken from Bulletin 160-93, shows a summary of current and projected water uses under average water year and drought scenarios. Definitions of water terms used in Table 1-1 are found on page 3.

Bulletin 166 Series

In 1968, the Department began the Bulletin 166 series focusing on urban water use in California. This bulletin periodically updates historical urban water use data.

Some objectives of the Bulletin 166 series are to:

- Prepare data and analysis for updating the *California Water Plan*, for use in other planning studies, and for general public information;
- Provide basic water use information including summaries of urban water production, delivery, and related data from local water agencies;
- Summarize historical water data and analyze trends in water use by hydrologic regions and major categories of use;
- Quantify self-supplied water use;
- Describe methods for forecasting future water requirements; and
- Assess the effects of water conservation practices.

Table 1-1. California Water Demand
(millions acre-feet)

Category of Use	1990		2020		1990-2020 Change	
	average	drought	average	drought	average	drought
Urban

Net water	26.8	28.2	24.9	26.1	-1.9	-2.1
Depletion	24.2	25.6	22.8	24.1	-1.4	-1.5
Environmental ¹						
Applied water	28.8	16.8	29.3	17.3	0.5	0.5
Net water	28.4	16.4	28.8	16.8	0.4	0.4
Depletion	24.4	12.9	24.7	13.3	0.3	0.4
Other ²						
Applied water	0.3	0.3	0.3	0.3	0.0	0.0
Net water	1.5	1.5	1.5	1.4	0.0	-0.1
Depletion	1.0	1.0	1.0	1.0	0.0	0.0
Total						
Applied water	68.0	58.0	71.1	61.2	3.1	3.2
Net water	63.5	53.2	65.7	55.3	2.2	2.5
Depletion	55.3	45.5	56.9	47.2	1.6	1.4

¹ Includes water dedicated to wetlands, instream flows, wild and scenic river flows, and salinity repulsion. There may also be 1 to 3 MAF in additional environmental demand.

² Other includes conveyance losses, recreation uses, and energy production.

Bulletin 166-1 (*Municipal and Industrial Water Use*, August 1968) compiled water use data from 1961 through 1965 on 85 water suppliers and major manufacturing facilities, presented as per capita water use on a daily, monthly, and annual basis. This was the Department's first report to present detailed urban water use data, including per capita water use data and projections for cities in the various hydrologic regions of the State.

Bulletin 166-2, *Urban Water Use in California* (October 1975) summarized monthly per capita water use data from 1961 through 1970 for 147 water service agencies throughout the State. This report noted, "Historic trends in per capita water use are generally continuing upward, although rates of use have leveled off or remained the same within a number of communities."

Bulletin 166-3, *Urban Water Use in California*, (October 1983) reported water use rates for 178 water service agencies (including those reported in Bulletin 166-2) from 1970-71, through 1980. This report noted, "After years of a generally upward trend, overall per-capita water use appears to have tended to level off during the past decade." This report recognized a marked drop in water use during the dry years of 1976 and 1977, followed by a return to previous levels of usage, but also conjectured, "Most major water suppliers in California have active water conservation programs, which should further tend to reduce future per-capita water use rates."

Bulletins 166-4 and 160-93 were developed concurrently and are based on the same urban water use data through 1990.

Other Department reports focus specifically on water use by manufacturing industries (Bulletin 124 series, last updated in 1982), and by agriculture (Bulletin 113 series, last updated in 1986).

Highlights of This Report

Bulletin 166-4 summarizes historical urban water use trends, per capita urban water use, applied and net water use and depletions, and type of use (residential, commercial, industrial, and governmental) during the period 1980 through 1990.

Applied Water Use, Net Water Use, and Depletions

Urban applied water means the water produced and supplied to the system of an urban water purveyor. Three other terms, also found in Appendix B, are important enough to be explained here:

ETAW (Evapotranspiration of Applied Water): The portion of the total evapotranspiration provided by irrigation.

Net Water Demand: The amount of water needed in a service area to meet all requirements. It is the sum of ETAW, irrecoverable losses from the distribution system and the outflow leaving the service area.

Depletion: The water consumed within a service area that is no longer available as a source of supply. For urban use it is ETAW from landscapes and gardens, sewage effluent that flows to a salt sink, and incidental evapotranspiration losses.

As in previous issues of this report, a major portion consists of 10-year summaries (Appendix A) of actual

monthly water use data as reported to the Department by nearly 300 retail urban water purveyors representing all 10 major hydrologic regions in California. These suppliers report populations in their service areas that range from a few hundred to over 3 million, totaling about 74 percent of the State's population. They deliver from less than 100 to over 650,000 acre-feet annually, and constitute about 90 percent of total urban water deliveries statewide. Appendix A includes regional maps and a listing of water suppliers reporting in this bulletin. The per capita values calculated for the water agencies in Appendix A are weighted by population for regional and statewide urban water use estimates.

Since the primary focus of this bulletin is on actual water-use history from 1980 to 1990, the effects of the 1987-1992 drought and conservation programs adopted by State and local agencies are evident in the data in Appendix A. In contrast, some of the analyses in this report and in Bulletin 160-93 use estimates for 1990 that are *normalized* by averaging 1980-87 data to eliminate the skewing effects of the drought.

Chapter 2 of this Bulletin describes and analyzes the four major sectors of urban water use and introduces terminology. Chapter 3 discusses climatic, socioeconomic, and demand management factors that influence water usage rates. Chapter 4 is a discussion of water pricing methods and policies. Chapter 5 discusses future water demands and illustrates an urban water-use forecasting model to evaluate the effects of water conservation management practices. Finally, Chapter 6 describes the data gathering processes used in acquiring the 1980-1990 water use data in Appendix A.

Even with aggressive conservation programs, urban water use will continue to increase as population grows.

Chapter 2.

Urban Water Use in California

Population Growth

Population estimates for 1990 and 2020 are based on census data and projections provided by the Department of Finance. State law mandates that these estimates are used in the Department's planning studies. Regional planning agencies, such as the Southern California Association of Governments, Association of Bay Area Governments, and others also prepare population projections.

The Department of Water Resources divides California into 10 major hydrologic regions (see Figure 2-1) for water planning. Each region is divided into planning sub-areas (PSA), which are further divided into detailed analysis units (DAU) (see also Appendix A). The Department's major water use bulletins incorporate data gathered and analyzed by DAU and aggregated to PSAs and hydrologic regions. Table 2-1 compares 1990 and 2020 urban population by hydrologic region.

Table 2-1. Urban Population by Hydrologic Regions (millions)

Region	1980	1990	2020
North Coast	0.5	0.6	0.9
San Francisco	4.8	5.5	6.9
Central Coast	1.0	1.3	2.0
South Coast	12.9	16.3	25.3
Sacramento River	1.7	2.2	4.1
San Joaquin River	1.0	1.4	3.2
Tulare Lake	1.2	1.5	3.5
North Lahontan	0.1	0.1	0.1
South Lahontan	0.3	0.6	1.9
Colorado River	0.3	0.5	1.0
Total	23.8	30.0	48.9

Population growth varies throughout the State. Growth rates are increasing in the hotter interior of California where residential per capita water use is greatest. Table 2-2 shows county population growth between 1980 and 1990.

Urban Applied Water and Per Capita Water Use

Urban applied water is the measured quantity introduced into a water supplier's system (water production) and is equivalent to water delivered to customers plus unaccounted losses. Urban applied water includes the water produced for all urban needs—residential, commercial, industrial, and governmental. Although, most urban water use occurs in urban areas, it also occurs in outlying rural-area residences, commercial facilities, manufacturing plants, and governmental facilities. See Appendix B for a glossary of terms.

Per capita water use is all applied water divided by the total permanent resident population of the water service area. The most difficult aspect of quantifying the per capita use is accurately determining population of the service area.

Table 2-3 presents normalized 1990 per capita water use by hydrologic region used in Bulletin 160-93. The normalized 1990 levels were calculated based on the average per capita use in more than 170 California communities during 1980 to 1987, a period unaffected by the 1987-92 drought. The averages also include estimates of self-supplied (not delivered by water purveyors) ground and surface water, estimated by the U.S. Geological Survey (1993) at over 550,000 acre-feet per year statewide.

The values in Table 2-3 represent gross per capita water use (see Glossary, Appendix B) including the residential, commercial, industrial, and governmental water use sectors. The residential per capita water use was based on the percentage of the total water delivered to residences in each region. The statewide average was calculated by weighting the per capita water use of each region by population. The heavily populated South Coast most strongly influenced the statewide average. These values reflect reductions in per capita use caused by conservation that have accumulated since 1980. It is estimated that urban applied water in the normalized 1990 year compared to 1980 was being reduced by about 435,000 acre-feet statewide due to ongoing conservation programs (Bulletin 160-93).

Table 2-2. Population Growth by County, 1980 to 1990

County	Total Population		% Growth 1980-1990	County	Total Population		% Growth 1980-1990
	1980	1990			1980	1990

Statewide Weighted Average*	232	134
*Average of 1980-87 data used as the 1990 normalized base for Bulletin 160-93, weighted by population.		

Figure 2-2 plots statewide annual changes in per capita water use between 1940 and 1990 in six major regions of the State. The two drought periods of 1976-77 and 1987-92 clearly affect the annual values. Department data from 1920 through 1970 indicates that daily per capita use increased by 1.7 gallons per year. However, per capita water use has remained relatively constant since 1970, except for the variations due to weather. During drought years trends were modified downward by imposed water use restrictions and voluntary efforts by users to reduce use.

The hydrologic regions with the highest total urban applied water use are the densely populated San Francisco Bay and South Coast. The relationship between population density and per capita use is discussed in Chapter 3 and Appendix D. Table 2-4 shows normalized demand by hydrologic region.

Table 2-4. Normalized 1990 Urban Applied Water Demand by Hydrologic Region (millions acre-feet)

Per capita use is considerably higher in the Central Valley and Colorado River regions where it may reach over 600 gallons in July, compared to less than 100 gallons in some North Coast Region communities during the same period. Maximum values occur in the Palm Springs area, due to tourism and intense summer heat, which raises evapotranspiration to high levels on golf courses and landscaped residential areas. Coastal populations are expanding eastward into these warmer climates, tending to increase the statewide per capita water use and partially offset the demand reductions gained through conservation efforts.

The gross per capita use method is useful for estimating statewide urban water demands. It is sometimes used to compare the water use of communities, which is not appropriate without evaluating all the factors affecting demand.

To illustrate how difficult it is to generalize about the factors affecting urban water use, data from pairs of communities having the same climate is shown in Table 2-5.

Figure 2-2. Urban Agency Supplied Per Capita Water Use in Selected Hydrologic Regions

Water Use in the Major Urban Sectors

The urban applied water and per capita values discussed previously include all categories of urban water use. The Department's urban water use analysis recognizes four classes of use: residential, commercial, industrial, and governmental. However, there is no statewide standard as to what constitutes each category. Some water agencies classify institutional with commercial and consider governmental as public use. In other agencies, multi-family residential may be included with commercial or combined commercial/residential. Commercial water use reflects the impact of tourist and recreational visitors on per capita values of the permanent local population. In Department analysis, residential uses include single-family dwellings, apartment units, and mobile (or manufactured) home parks. The other three classes have been defined from the groupings established in the *Standard Industrial Classification Manual* published by the U.S. Office of Management and Budget. As described in the Manual: "The Standard Industrial Classification (SIC) is the statistical classification standard under-

lying all establishment-based Federal economic statistics classified by industry. The SIC is used to promote the comparability of data describing various facets of the U.S. economy. The classification covers the entire field of economic activities and defines industries in accordance with the composition and structure of the economy. . . ." The major SIC groups that the Department uses for the industrial, commercial, and governmental categories are identified in this chapter.

Some of the water produced by urban water agencies is unaccounted for in customer deliveries. In California, regional unaccounted water, whether authorized use, unauthorized use, or distribution system losses, commonly ranges between 6 and 15 percent. Agencies that received leak detection grants from the State in 1984—serving 13 percent of the State's population—showed an average 10-percent loss.

Figure 2-3 and Table 2-6 illustrate the percentages of water use in all water use sectors statewide and by hydrologic region.

Figure 2-3. 1990 Urban Applied Water Use By Sector¹

Residential Water Use

The largest single urban water-using group is residential water users, which comprised about 58 percent of the statewide total of urban water use in 1990. The largest users are single-family dwellings that customarily have individual front and rear landscaped areas requiring irrigation during the growing season. Apartments share the water used for common gardens and turf and as a result, per capita water use is smaller. Other multi-family group dwellings such as condominiums, duplexes, halfplexes, and mobile homes in parks have a wide range in water use depending on climate, lot size, and the extent of landscaping. Table 2-7 shows the percentage of residential use and total applied water for residential use in California's hydrologic regions. Since 1980, the percentage of residential use, in relation to total urban use, has increased 4 percent.

The categories of interior residential water use were shown as percentages, not as volumes of water in the *California Water Plan Update* (DWR Bulletin 160-93). However, *Water Conservation in California* (DWR Bulletin 198, May 1976) separated volumes of urban water use into the categories displayed in Table 2-8. For this report, the percentages found in Bulletin 160-93 have been used to calculate the volumes shown in Table 2-9.

Interior Use	Percentage of Total Interior Use	Total Applied Use (1,000 AF)
Toilet	36	840
Bath/Shower	28	650
Dishwashing	3	70
Laundry	20	460
Faucets	13	300
Total	100	2,320

Source: Adapted from Table 6-7, Bulletin 160-93 (November 1993 draft)

Because of low-flow fixture laws and conservation efforts during the 1980s, the percentage of total urban use in toilets and baths has declined from 56 percent of gross urban water use in 1972 to 51 percent in 1990. All faucets and showerheads manufactured after January 1, 1994, were restricted to a flow of 2.5 gallons per minute as established in the Federal Energy Policy Act of 1992. Further, all water closets sold or installed in California must use no more than 1.6 gallons per flush under State and federal laws. These and other factors should cause interior water use to decline per person but the increase in population will cause the total water used in residences to increase.

While gross indoor residential applied water use has increased, it has not increased as rapidly as population

growth. Comparison of the 1972 and 1990 data in Table 2-8 and Table 2-9 shows an increase of 24 percent in interior use while population increased 43 percent. In contrast, applying the same analysis to exterior water use, predominantly landscaping (discussed in Chapter 3), shows an increase of 44 percent over the same period while population increased 43 percent.

Commercial Water Use

The percentage of commercial water use rose during the 1980s from 14 percent to 17 percent of total urban use. In Bulletin 166-3, the commercial sector included office buildings, restaurants, and other business establishments, but excluded governmental uses. The commercial categories based on SIC codes included:

Division	Description	Codes
C	Construction	15-17
E	Transportation, Communication, etc.	40-49
F	Wholesale Trade	50-51
G	Retail Trade	52-59
H	Finance, Insurance and Real Estate	60-67
I	Services	70-89
K	Non-classifiable Establishment	99

This bulletin uses the same categories to describe commercial use. However, commercial water use data are not gathered by category. In addition, there are methods of classifying urban water use that combine commercial and some governmental categories. There is little reason to assume that water use in a privately-owned hospital differs significantly from a University of California Medical Center in the same geographic location. A standardized grouping of SIC codes to describe commercial water use would be useful.

The regional commercial water use is illustrated in Table 2-10. Two other factors making the data on commercial use relatively *soft* are that multi-family housing units are often classified as commercial by local water agencies and that there is little data on the amount of commercial water use that is self-supplied. The U.S. Geological Survey (1993) estimated that 26 percent of all commercial use is self-supplied.

South Lahontan	13 12-6	25
Colorado River	22	66
Average	17	Total 1,329

* Average of 1980-87 data used as the 1990 *normalized* base for Bulletin 160-93

Generally, broad commercial services develop in proportion to industrial, military, or governmental development. With its overall mild climate, the most populous state also abounds with tourist and recreational services year round and in most regions. The San Francisco Bay Region, North Lahontan (Lake Tahoe is in this region), and the Colorado River Region (Palm Springs) have the highest percentages of commercial use. The highly urbanized South Coast Region, which dedicates 80 percent of its total water demand to urban uses, has growing commercial water use (700,000 acre-feet) due to the growth in services and tourism.

In previous bulletins, the Department did not estimate volumes of water used in this category by hydrologic region. This is a growing category of urban water use that needs to be analyzed more completely in the 1990s.

The East Bay Municipal Utility District (1992) estimated that the 1986 actual demand of commercial enterprises was 15 percent of its applied water demand. Similarly, the base year (1990) projection of water use in The Metropolitan Water District of Southern California (Planning and Management Consultants, 1990) indicated that 17 percent of the use was commercial.

Industrial Water Use

The Department's Bulletin 124-3, *Water Use by Manufacturing Industries in California* (May 1982), identified a number of water intensive manufacturing industries including SIC Major Groups:

- 20: Food and Kindred Products
- 24: Lumber and Wood Products, Except Furniture
- 26: Paper and Allied Products
- 28: Chemical and Allied Products
- 29: Petroleum Refining and Related Industries
- 32: Stone, Clay, Glass, and Concrete Products
- 36: Electronic and other electrical equipment.

As of 1990, 8 percent of urban water deliveries are received by manufacturers, representing a decrease of 6 percent since 1980. Industrial water use in the hydrologic regions of California is shown in Table 2-11.

In areas where these water-intensive industries are sited, overall per capita water use may be higher than in areas without these industries. Where water-intensive industries exist, much of the industrial supply may be self-produced rather than utility supplied. Where this occurs, this additional amount of water must be identified and added to the amount distributed by water agencies before per capita rates can be calculated. Bulletin 124-3 estimated that 58 percent of the fresh water supplied to manufacturing plants in 1979 was agency-supplied, while 42 percent was self-supplied through wells, diversion, or springs. The U.S. Geological Survey (1993) indicated that approximately 25 percent of fresh industrial water was self-supplied in 1990. A survey of industrial use in 12 San Francisco Bay Area and Southern California counties indicated that 18 percent of their water was self-supplied (California Urban Water Agencies, 1990). However, the data are limited for the Central Valley, where it is assumed much of the industrial water is self-supplied because of accessible ground water. Twenty-five percent of industrial water was assumed to be self produced in 1990 for this Bulletin.

The total industrial water use of 620,000 acre-feet shown in Table 2-11 is almost a 300,000 acre-feet reduction from the 918,000 acre-feet reported in Bulletin 124-3 for 1979. While this is a rough approximation, it does show that the Clean Water Act of 1972 and its amendments in 1977, along with industrial conservation programs and a de-

cline in the lumber industry, have been important factors in reducing water use.

Table 2-11. Industrial Applied Water Use in California*

Region	Percentage	Applied Water Use (1,000 AF)
North Coast	14	24
San Francisco	9	107
Central Coast	8	22
South Coast	8	304
Sacramento River	6	44
San Joaquin River	10	49
Tulare Lake	10	52
North Lahontan	23 (26) ~	9
South Lahontan	1 T 2-6	2
Colorado River	2	6
Average 8		Total 619
* Average of 1980-87 data used as the 1990 <i>normalized</i> base for Bulletin 160-93		

The highest percentage of industrial water use in relation to total urban use is the pulp and lumber industry in the sparsely populated North Coast Region. In the San Francisco Bay Region, high-water-using industries include oil refining and electronics. Even with the decline in the steel, aerospace, and defense industries in the South Coast Region, it remains the largest manufacturing center in the United States. Industrial water use in the Central Valley remains dominated by the food processing, concrete, and chemical industries and petroleum refining in the Tulare Lake Region.

Governmental/Public Water Use

The percentage of total water use in this category declined 1 percent from 1980 to 1990. Most governmental users are classified and described in the SIC Manual, Division J, Public Administration. This division includes the executive, legislative, judicial, administrative, and regulatory activities of federal, State, local, and international governments. As was done in Bulletin 166-3, the Department has expanded the category to include all public functions that may not have been specifically identified in the SIC Manual, such as schools, public offices, military installations, public parks, public cemeteries, and golf courses, and other public-controlled entities. There are frequent cases of overlap with commercial activities

such as golf courses and hospitals. The use of the SIC code for this category may need to be modified in the future.

The governmental water use data presented in Table 2-12 may not be consistent with locally derived data because of the inclusion of many users considered in commercial or irrigation categories by others. Many types of governmental activities will use nearly the same water as similar commercial enterprises. Some current forecasting techniques group much of this category with commercial and use the public/other category for the remainder.

Table 2-12. Governmental Applied Water Use in California*

Region	Percentage	Applied Water Use (1,000 AF)
North Coast	5	8
San Francisco	7	83
Central Coast	6	16
South Coast	6	228
Sacramento River	12	89
San Joaquin River	6	29
Tulare Lake	4	21
North Lahontan	10	4
South Lahontan	14	27
Colorado River	3	9
Average 7		Total 514
* Average of 1980-87 data used as the 1990 <i>normalized</i> base for Bulletin 160-93. Does not include military bases.		

There was no analysis of the total volume of governmental use in past bulletins; however, it has shown a slight percentage decrease of gross urban use since 1980.

Unaccounted Water

Unaccounted water was not identified in Bulletin 166-3. However, water production ranges from about 6 to 15 percent higher than water ultimately delivered to customers in each hydrologic region. The difference between water production and delivery to customers is called *unaccounted water*, which consists of actual losses in the delivery system including authorized and unauthorized uses.

Table 2-13 shows that the proportion of unaccounted water varies substantially in each region of the State. The quality of this data in the Central Valley is affected by the lack of residential metering in many areas.

Table 2-13. Unaccounted Water in California*

Region	Percentage	Water Use (1,000 AF)
North Coast	14	24
San Francisco	8	95
Central Coast	10	27
South Coast	9	342
Sacramento River	9	67
San Joaquin River	6	29
Tulare Lake	9	47
North Lahontan	15 (7) 10	6
South Lahontan	10 7 20	19
Colorado River	14	42
Average	10	Total 698
* Average of 1980-87 excluding drought years.		

System losses were reported at about 8 percent for the City of Sacramento (Boyle Engineering, October 1991), 9 percent for EBMUD in 1986 (EDAW, December 1992) and 9 percent for MWD (PMCL, February 1990).

The percentage of statewide urban water that is unaccounted for has remained about the same between 1980 and 1990. There have been aggressive leak detection and repair programs by the Department and some local agencies. Such programs reduce urban applied water and are cost effective in most cases. The results of the Department's 1984 program managed by the Water Conservation Office were published in the *Water Engineering and Management Magazine* (May 1987). The program found that:

- an average of the 57 cooperating agencies found 10 percent unaccounted water,
- the maximum unaccounted water was 30 percent,
- over 2 years, almost 16,000 acre-feet were recovered, and

- the benefit-to-cost ratio was almost three to one.

The results of this study indicate that substantial amounts of water could be conserved statewide by aggressive leak detection and repair programs implemented on a large scale.

Effects of Drought and Water Conservation on Urban Applied Water

The 1976-77 drought had a severe and immediate impact on per capita water use through enforced rationing programs and voluntary efforts on the part of water users. However, after recovery from the drought in 1978, a trend toward predrought consumption clearly began. Previous per capita use rates were reached in 1981 and slightly exceeded in 1984. Succeeding years were level until the start of the 1987-92 drought. When constraining measures were reinstituted about 1988, consumption rates again fell. Under these circumstances, it is difficult to assess the real effect of conservation education and other persuasive measures responsible for a general leveling of per capita water use.

The increase in water conservation efforts over the past 20 years is also forcing other changes in the way we manage water supplies. During the drought of 1976-77, many agencies were able to reduce per capita water demand sharply through a variety of water conservation measures. As more conservation measures are adopted, making permanent changes in the way we use water, there is less flexibility to reduce per capita use during droughts and other shortages. Estimates made in Bulletin 160-93 indicate that 435,000 acre-feet of urban applied water were conserved in 1990 compared to 1980, and that an additional 1,285,000 acre-feet of applied water reductions will occur by 2020 due to BMPs (Table 2-14).

Table 2-14 estimates 2020 urban applied water reduction and reductions in depletions for each hydrologic region of California.

Water Recycling and Gray Water

Two other water management options, reclamation and gray water use, are getting increasing attention in California.

The 1990 level of water recycling is based on evaluation of data presented in Bulletin 160-93 from the report *Water Recycling 2000* (September 1991). Table 2-15 displays recycled volumes for 1990 by hydrologic region. The estimated type of recycling by percentage of the total volume is shown in Figure 2-4.

Bulletin 160-93 also projected that an additional 967,000 acre-feet per year would be produced by 2020 based on a recent report by the WaterReuse Association of California (July 1993).

In 1992, the California Legislature approved and the Governor signed Assembly Bill 3518 to permit statewide use of gray water for landscape irrigation. The California Plumbing Code (Title 24, Part 5, California Administrative Code) defines gray water as untreated household waste water that has not come into contact with toilet waste.

Figure 2-4. Estimated 1990 Water Recycling by Category

Adapted from *Water Recycling 2000*, September 1991, State Water Conservation Coalition Reclamation/Reuse Task Force and the Bay Delta Reclamation Sub-work Group. Estimated 1990 use of reclaimed water is based on actual 1989 use reported in *Water Recycling 2000*.

Gray water use could help reduce the demand for potable fresh water over the long term. Most households produce between 24 and 36 gallons of gray water per person per day. Many population centers in California are located in areas where the climate requires landscape irrigation at least 7 months of the year, so gray water could replace potable water during that time. Gray water would generally only be practical in larger lots where adequate side clearances can be maintained for subsurface irrigation fields.

A more substantial use of gray water in residential areas would require major investments in plumbing and may not be practical for existing housing. The expected population increase between 1990 and 2020 is about 19 million people. If half these people live in single-family dwellings in new housing with gray water plumbing, the potential for gray water use, at 30 gallons per person per day, could be about 180,000 acre-feet of water in 2020.

California's climate, weather, demographic patterns, and other factors influence water demands.

Chapter 3. Factors Influencing Urban Water Use

This chapter discusses climatic, socioeconomic, and water conservation factors that influence per capita water use. More information on climatic factors is found in Appendix E.

Climatic Factors

Climate has a great overall influence on annual and seasonal changes in per capita water use. Climatic factors (temperature, precipitation, solar radiation, humidity, wind) operate in combination to influence the amount of water consumed by plants. Their effects differ with locality and fluctuate seasonally and from year to year.

The sun is the original source of all energy involved in the transformation of water from liquid to vapor. Solar radiation provides the energy for photosynthesis and plant growth. Factors such as humidity, wind, and temperature originate as a result of solar radiation. For this reason, California's sunny inland valleys have much higher rates of water use than coastal areas.

Temperature is the climatic factor that most influences the water use of landscape vegetation. Seasonal per capita water use values reflect the changes in urban landscape water demands as users respond to changes in temperature.

Precipitation most effectively reduces the need for supplemental landscape irrigation water when it occurs during late spring through early fall when vegetation is actively growing. In winter, landscape water requirements are sharply reduced when dormancy, or near dormancy, of warm weather turf species such as Bermuda grass and ornamental shrubs and trees lowers or eliminates the need for irrigation.

High humidity suppresses plant water use. The evaporating power of the atmosphere increases under drier conditions, causing water to be used at a greater rate by plants. In coastal areas, the humidity remains uniformly high because of proximity to the ocean and prevailing westerly winds.

Wind accelerates water use. Air movement removes saturated air from contact with moist soil, water, and leaf surfaces and replaces it with warmer and drier air from adjacent areas. Plants exercise partial control over water loss from their leaves, while moisture loss from water and soil surfaces increases in relation to wind speed.

Evaporative Demand

The evaporative demand is the cumulative influence of these climatic variables on the rate of water evaporation. Numerous studies have shown that water evaporation from a standard water surface resolves the climatic influences into one easily measured variable that closely correlates to plant water use. The standard water surface most commonly used in California is the U.S. Weather Bureau Class A evaporation pan.

Evapotranspiration

The climatic factors mentioned previously drive the processes of evapotranspiration (ET). The components of ET are transpiration, the movement of water through the leaves into the air as vapor to cool the plant, and evaporation of water from the plant surface or soil adjacent to the plant.

Evaporative demand based on evaporation of water from a standard U.S. Weather Bureau Class A evaporation pan in an irrigated pasture or equivalent environment can be used as an index for evapotranspiration.

The evapotranspiration of cool-season grass, or *reference* evapotranspiration (ET_b) can be used as an index of landscape water requirements. The map in Figure 3-2 (previously published in DWR Bulletin 113-3) shows average annual ET_b in California. These values range from 30 inches in the extreme northwest in Del Norte County to more than 90 inches in the desert of southeast California.

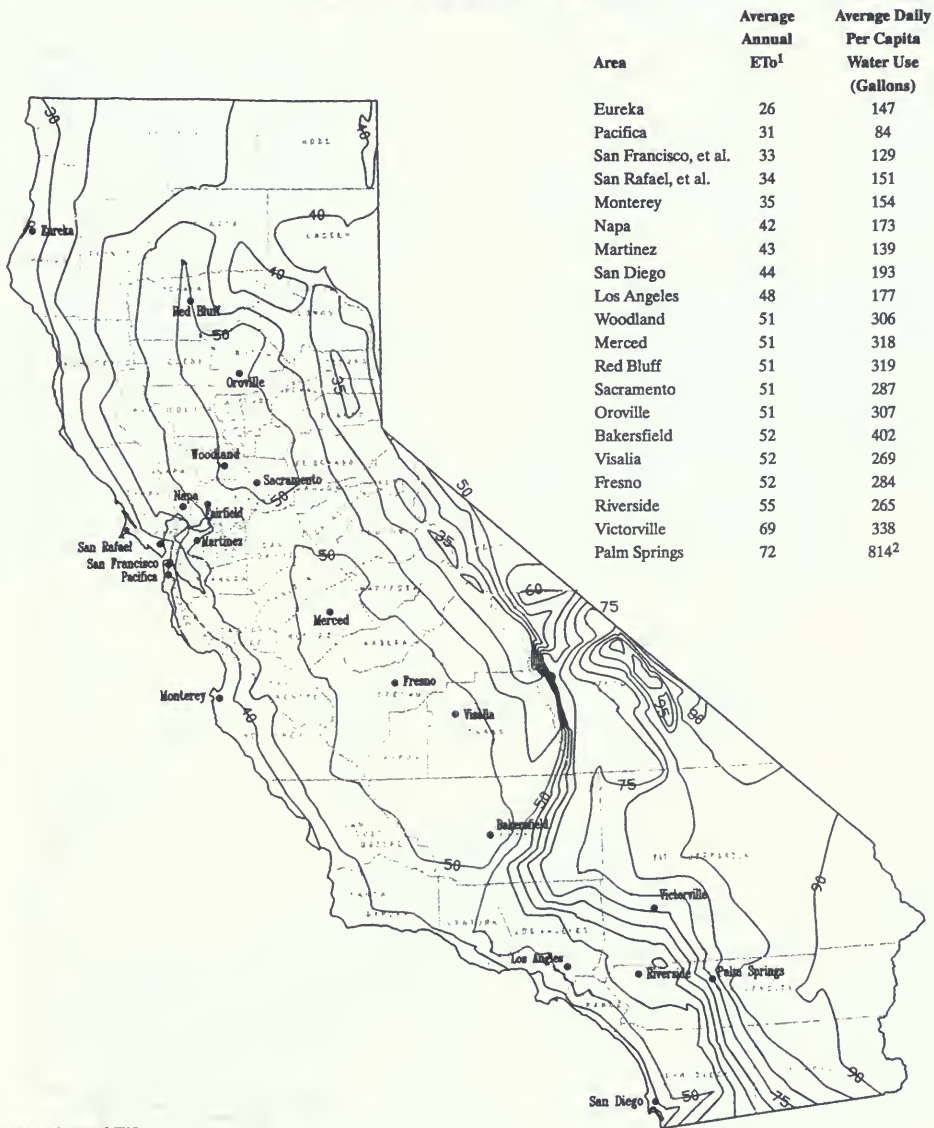

The lines of equal average annual ET_b extend generally from north to south, with higher values in the south. The 60-inch iso-line is characteristic of the Central Valley and also extends through Central Los Angeles County. The hot summers in the Central Valley are offset by the warm-

er winter climate in Los Angeles, resulting in about the same average annual ET₀ for both areas. The effect of seasonal variations in ET₀ on plant water use is reflected in per capita water use values.

As determined by the Department, variations in per capi-

ta water use and ET₀, precipitation, and July temperatures for 20 communities in California are displayed in Figure 3-1, Figure E-1, and Figure E-2 (Appendix E) respectively. These figures indicate that climatic factors alone cannot explain all differences in per capita use.

Seasonal Water Use

The variation in seasonal water use in any water year is directly related to the variation in the climatic and meteorological factors. Previous issues in the Bulletin 166 series focused primarily on outdoor use and its relationship to evapotranspiration. The seasonality of water use is represented in Figure 3-3. This graph also illustrates how the seasonality of water use varies depending on the type of water year. The water use between October and April increases in drought years versus average water years because less precipitation means more landscape irrigation.

A thorough discussion of the seasonality of water use is found in Seasonal Components of Urban Water Use in Southern California (PMCL, 1990). The seasonal use was derived by the minimum month method of analyzing water use records. Although most of the residential seasonal water use is due to landscape irrigation, the seasonal variation in commercial, industrial, and governmental uses is the result of space cooling and process cooling needs as well. The seasonal water uses related to the categories of use in Southern California are displayed in Table 3-1.

Seasonal Use: An aggregate of end uses of water (e.g., lawn watering, cooling) that varies from month to month in response to weather conditions and other seasonal influences.

Nonseasonal Use: An aggregate of end uses of water (e.g., toilet flushing, washing machine use) that remains fairly constant from month to month because these end uses are not sensitive to weather conditions and other seasonal influences.

Minimum Month Method: Seasonal and nonseasonal components of urban water use in the major classes are often estimated by the minimum month method. For a given year, this method first determines the month of lowest use; this amount is assumed to be constant throughout the year. By definition, seasonal use is zero in the minimum month and will vary with weather conditions during the remaining months. Seasonal use typically peaks during the hottest summer months.

For this bulletin, the Department analyzed water production data from 1980-87 for 68 cities in various regions of California using the minimum month method. Transects were followed from the coast to the interior. The percentage of seasonal use is displayed in Table 3-2.

Table 3-2. Percentage of Seasonal Urban Water Use in Various Regions of California

Region	Coastal Plains	Coastal Valleys	Interior Valleys
Northern	26	--	55
Central	39	47	56
San Joaquin	32	47	58
Southern	34	38	54

Figure 3-4 illustrates the annual variation in seasonal water use for Los Angeles and Fresno based on the minimum month method. While baseline water use for both cities is essentially the same, the seasonal use in Fresno is greater due to the large landscape irrigation requirement during summer in the Central Valley. The large sea-

sonal component reflects in Fresno's annual per capita water use. Table 3-3 compares baseline and peak seasonal use, percentage seasonal use, and annual per capita use for Los Angeles and Fresno.

Table 3-3. Comparison of Seasonal Water Use and Annual Per Capita Water Use in Los Angeles and Fresno During 1980-87

	Los Angeles	Fresno
Baseline use (gpcd) (March 1982)	127	128
Peak seasonal use (gpcd) (July-Aug 1984)	90	342
Percentage seasonal use	30	55
Annual per capita water use (gpcd)	186	284
Source: DWR data (Appendix A)		

Seasonal Versus Outdoor Use

The difference between seasonal water use and outdoor use may need further explanation. Since landscape irrigation, car washing, etc., may occur in any month of the year, the minimum month method may underestimate outdoor use and, therefore, overestimate indoor use. Indoor water use may also increase during the summer.

The PMCL seasonal use study (February 1990) indicated that outdoor use was almost 9 percent higher than that estimated by seasonal use in Southern California. Of the outdoor use, 90 percent in the residential sector and 84 percent in the non-residential sector was due to irrigation.

For the statewide analysis of urban water use in this bulletin, it is assumed that the minimum month determined over the 7-year period (1980-87) approximates indoor use. This is considered a valid assumption because the difference in volume of water between seasonal and outdoor use is small and affects the statewide analysis of total urban water use very little.

**Figure 3-4. Allocation of Seasonal and Base (nonseasonal)
Water Use Using Minimum Month Method
Los Angeles and Fresno**

Los Angeles

Fresno

Note: Seasonal use does not reach the base level because some largely seasonal uses, such as irrigation, occur in small amounts during the winter.

Socioeconomic Factors

Climatological factors help explain much of the water use in various regions. Other factors affecting water use range from economic to esthetic factors and cover a wide range of activities.

Income

A previous Departmental study found that personal income correlates with unit water use in various areas of the South Coast study area (DWR, 1959). Cities with a large per capita income generally used more water per capita than cities with lower per capita income. A recent update of that report shows a similar relationship of consumption of water to household income that is illustrated in Figure 3-5.

Large residential lots in higher income areas require more irrigation water and water costs tend to constitute a smaller fraction of the household financial budget. Also, higher income families may own more water-using appliances. However, this trend may not be as obvious currently because most families have major appliances.

Swimming pools are normally associated with higher income families in single-family residences. One method estimates that swimming pools, compared to ordinary landscaping, add about 40 gallons per housing unit per day to single-family residential use in Southern California (PMCL, 1990).

Evaluating Urban Water Conservation Programs: A Procedures Manual (February 1992), a report prepared for California Urban Water Agencies supports the presumption of higher water consumption with higher income levels. It states, "Empirical studies clearly show that increasing income (in real terms) will cause an increase in water use in the residential sector." The elasticity of income in single-family sectors varies from 0.3 to 0.6. This means that a 10 percent increase in income may cause a 3 to 6 percent increase in water use. Further, a number of new urban water-use-forecasting methods include income as one explanatory variable.

Water Price

Water pricing structures generally serve as a means for water suppliers to recover costs of delivery to the end users. When California's developed water supply was deemed more than adequate to serve the existing popula-

tion, urban water suppliers used a declining block pricing structure, where the unit cost varied inversely to the quantity of water used. As water shortages have become more common, suppliers have tended to discontinue such rate structures.

Pricing can work to influence demand by providing an incentive for customers to manage water use more carefully. The customer's sensitivity to pricing may be enhanced by rate structures that increase the cost of water at a constant or increasing rate as use increases.

Chapter 4 contains a detailed discussion of water pricing that is continued in Appendix F.

Water Meters

Today, virtually all large communities in California are at least partially metered. In 1991, Senate Bill No. 229 enacted the Water Measurement Law (Section 110 of Chapter 8 of Division 1 to the Water Code) requiring all new potable water service connections be metered after January 1, 1992. Generally, commercial and manufacturing businesses (other than self-supplied) have been metered for many years. Some unmetered or partially metered communities are still found in the Central Valley, foothills, and mountains, primarily involving residential accounts.

Bulletin 166-1 (DWR, 1968) documented the effects of metering in the San Joaquin Valley (southern portion of the Central Valley). It reported a 42 percent lower per capita water use in metered cities compared to flat rate communities. This study compared metering of all water users rather than restricting the study to only residential users. *A Study of the Proposed Requirement for Mandatory Water Metering for Municipalities or for Domestic Water Systems* (Arthur D. Little, Inc., 1974) showed that flat-rate services in 1970 averaged 330 gpcd in the Central Valley of California compared with 230 gpcd for metered cities, a 43 percent difference. However, this report also concluded that (1) the cost of metering may outweigh its benefits, (2) non-metered cities normally are close to inexpensive supplies, and (3) effective metering could cause landscaping to bear the brunt of water savings. Currently, metering would not have as dramatic an effect because of conservation activities causing a "hardening" of demand.

Generally, metering caused a reduction in water use and provided useful planning data for establishing a rate structure. While there is still opposition to metering in

parts of the Central Valley and other outlying areas, the trend toward metering all deliveries in California continues. In some agencies, metering and pricing are linked to indoor versus outdoor water usage.

Water-Using Appliances and Other Household Uses

More water-using household appliances came into use during this century. A variety of these water-using or water-operated fixtures were added to homes and early models were not designed to save water. This contributed to increasing per capita water use trends. Most newer models on the market now require far less water than their predecessors. For example, new horizontal axis washing machines are being introduced that reduce indoor water use further. The introduction of new water-using devices is also diminishing.

Community Make-up

A number of sizeable communities surrounding large metropolitan areas and within commuting distance of city centers have developed as *bedroom communities* for people working in industrial and commercial city core areas. Bedroom communities generally expand rapidly, but initially have little growth in job-supporting industries.

As bedroom communities enlarge, they sometimes develop their own manufacturing and services industries and become more self-sufficient. For example, in recent decades communities in San Mateo County that were formerly small residential satellites of San Francisco have matured into predominantly industrialized areas. This increased industrialization in San Mateo County and in neighboring Santa Clara County has led to higher local per capita water use rates.

Water use trends are affected by changes in the patterns of land use. As cities age and enlarge, the centers are progressively rezoned for higher population density uses under urban renewal or similar programs. Single-family dwellings are replaced by multiple-unit structures with some land set aside for commercial strips and other industrial development.

In a small community, the addition or removal of a single high-water-using entity, such as food processing, of significant size can noticeably increase or decrease the per capita water use. The effect can be less pronounced for a major city where one addition or removal of a water-intensive industry may have minimal impact.

Many communities have an influx of non-residents (daily, on weekends, or seasonally) who are probably counted as permanent residents of another community and are not considered in per capita water use calculations. Relying solely on gross per-capita use values in these communities can be misleading.

Residential Density

Population density is higher in apartments than in single family dwellings. Per capita interior household water use is slightly higher in single family homes than apartments. Also, the rate of exterior water use to irrigate landscape for apartment dwellers is somewhat less than for persons living in single family dwellings, due in part to more persons sharing the landscaped area. For example, in the Metropolitan Water District service area, the average outdoor use was 92 gpcd for single family dwellings and 79 gpcd in multifamily units (MWD, 1990).

Between 1970 and 1980, there was a decrease in the percentage of single-family dwellings to multiple-family households. This trend leveled off in the 1980s. Table 3-4 shows the percentages of single family and multiple family dwellings in California between 1970 and 1990. The reduction in proportion of single-family dwellings led to the leveling in the statewide per capita water use.

Table 3-4. Percentage of Single and Multi-Family Households in California

	1970	1980	1990
Single Family	75.9	63.1	62.7
Multi-Family	24.1	36.9	37.3
Total	100.0	100.0	100.0

Persons per Household

In 1970, an average of 3.3 persons lived in single family dwellings and 2.4 persons occupied the average apartment unit (Table 3-5). The overall effect of the decrease in persons per household during the 1970s was to increase per capita water use by increasing landscape water requirements per person. Conversely, increasing persons per household lowers per capita residential water use. An increase in persons per household, which occurred during the 1980s, contributed to a leveling of the statewide gpcd.

Table 3-5. Persons Per Household by Housing Type

	1970	1980	1990
Multi-Family	2.4	2.1	2.3
Single Family	3.3	3.0	3.1
All Households	3.1	2.7	2.8

Water Conservation

In recent years, urban water conservation has contributed to the leveling off of the historically upward trend of per capita water use, even before the droughts of 1976-77 and 1987-92. In the early 1970s, a number of California water suppliers established conservation programs and the State increased its efforts to disseminate information and help local agencies implement programs to reduce water consumption. The need to stretch existing water supplies to meet the needs of a growing population was recognized.

The 1976-77 drought helped prompt the incorporation of water demand management into the State's laws and institutions. California was the first state to establish efficiency standards for toilets in 1978. The same year, the California Energy Commission established flow rate standards for shower heads and faucets, conserving both water and the energy used to heat it.

A report prepared for the California Urban Water Agencies by the Planning and Management Consultants, Ltd. (February 1992), states that "... an important change in water supply planning involves the use of water demand management (or water conservation alternatives). . . Comprehensive water supply management requires the evaluation of two basic sets of alternatives: (1) those alternatives that reduce water use and/or loss, and (2) those alternatives that augment supplies. Taken together, these alternatives provide the basis for efficient water management."

Urban Best Management Practices

As a result of hearings held by the State Water Resources Control Board on water rights affecting the San Francisco Bay and Delta, a coalition of urban and environmental water interests formed the California Urban Water Conservation Council. In 1991, the Council developed a voluntary Memorandum of Understanding that will lead to implementation of 16 Best Management Practices for urban water users and requires signatories to report on their status of implementation of the BMPs. The Council is continuing its efforts toward quantifying the effects of these practices and developing guidelines to help water suppliers determine the effectiveness of BMPs for their systems.

As of May 1994, 111 water suppliers, serving at least 80 percent of the State's population, plus 16 public advocacy

groups and 47 other interested parties, had signed the MOU.

Initial Best Management Practices. As stated in the MOU, the initial BMPs that signatory water suppliers have committed to implement are:

1. Interior and exterior water audits and incentive programs for single family residential, multifamily residential, and governmental/institutional customers.
2. Plumbing, New and Retrofit.
 - a. Enforcement of water-conserving plumbing fixture standards including requirements for ultra low flush (ULF) toilets in all new construction beginning January 1, 1992.
 - b. Support of State and federal legislation prohibiting sale of toilets using more than 1.6 gallons per flush.
 - c. Plumbing retrofit.
3. Distribution system water audits, leak detection, and repair.
4. Metering with commodity rates for all new connections and retrofitting existing connections.
5. Large landscape water audits and incentives.
6. Landscape water conservation requirements for new and existing commercial, industrial, institutional, governmental, and multifamily developments.
7. Public information.
8. School education.
9. Commercial and industrial water conservation.
10. New commercial and industrial water use review.
11. Conservation pricing.
12. Landscape water conservation for new and existing single family homes.
13. Water waste prohibition.
14. Water conservation coordinator.
15. Financial incentives.
16. Ultra low flush toilet replacement.

Potential Best Management Practices. The MOU commits the California Urban Water Conservation Council to study potential measures to determine whether they meet the criteria to be designated as BMPs. These include:

1. Rate structures and other economic incentives and disincentives to encourage water conservation.
2. Efficiency standards for water using appliances and irrigation devices.
3. Replacement of existing water using appliances (except toilets and showerheads whose replacements are incorporated as Best Management Practices) and irrigation devices.
4. Retrofit of existing car washes.
5. Gray water use.
6. Distribution system pressure regulation.
7. Water supplier billing records broken down by customer class (e.g., residential, commercial, industrial).
8. Swimming pool and spa conservation including covers to reduce evaporation.
9. Restrictions or prohibitions on devices that use evaporation to cool exterior spaces.
10. Point-of-use water heaters, recirculating hot water systems and hot water pipe insulation.
11. Efficiency standards for new industrial and commercial processes.

Over time, additional cost-effective measures will probably be identified and implemented as technology improves and alternative supplies become more expensive.

Urban Water Management Planning Act

Assembly Bill 797 enacted the Urban Water Management Planning Act in 1983. As an amendment to the Water Code, this act requires urban water suppliers serving more than 3,000 customers or more than 3,000 acre-feet annually to prepare and file with the Department a comprehensive water management plan including specified elements. The first plans were due in 1985, with updates required at least every 5 years. Currently over 300 public and privately owned water suppliers are reporting.

Landscape Water Use and Conservation

Landscape water use is directly related to a community's climate, makeup, housing mix, population density, and income.

In recent years, the Department's Agricultural Mobile Lab Program has focused on landscape irrigation system evaluations. During 1992, the Department contracted

with UC Davis (Bowers and Hanson, 1993) to analyze 363 landscape irrigation evaluation reports in San Diego, Riverside, and Ventura counties. The mobile lab program was developed primarily to provide management direction and not to gather basic data. However, the data on distribution uniformity and irrigation efficiency are certainly useful when only a few landscape water-use data sets are available. The distribution uniformity and irrigation efficiency statistics are presented in Table E-1 (in Appendix E) and Table 3-6 respectively.

Although difficult to apply to landscapes, the methods developed to estimate landscape water use are based on concepts developed for agriculture. Landscapes include a wide variety of species, planted in different densities and in varying microclimates (Table E-2). UC Cooperative Extension Leaflet 21493 (1991) suggests an approach for developing an overall landscape coefficient based on a species factor, density factor, and microclimate factor. This coefficient is determined by multiplying the three factors found in Table E-2.

Table 3-6. Statistics for Irrigation Efficiency for Landscapes Evaluated by the Mobile Irrigation Laboratory

District	N	Mean	Min	Max	Range
Ventura	12	69.1 a	30	103	73
Riverside	106	61.3 a	17	96	79
Mission	24	59.9 a	8	87	79
Coachella	149	41.6 b	13	84	69

Source: *An Analysis of Mobile Laboratory Irrigation System Evaluation Data: Urban Systems*, University of California, Davis, 1993

Probably the most comprehensive publication on landscape water efficiency was published by the American Water Works Association (Bennett and Hazinski, 1993). This publication discusses the water-budget approach, where landscapes are metered, and the checklist approach for unmetered landscapes.

Water demands for landscaping is expected to increase as population growth moves inland. In examining the data for 1980 from Bulletin 198-84 (DWR, 1984) about 2 million acre-feet were allocated to exterior landscape uses in California. By 1990, this value had risen to over 3 million acre-feet.

PMCL (1991) analyzed residential landscape irrigation in Southern California. In this study, households with

deficit irrigations exceeded households with surplus irrigations 56 percent to 44 percent. The actual percentage of deficit irrigation is probably higher than reported because all rainfall was considered effective at reducing the irrigation requirement.

In North Marin Water District, a study on water savings from irrigation scheduling on large turf sites at schools and parks (classified as governmental) showed that a 16 percent reduction in water usage could be expected (NEOS Corporation, 1991). However, a similarly scheduled private park showed a water savings of only 7.7 percent.

A study carried out for East Bay Municipal Utility District (1992) compared daily water consumption for single family homes having water-conserving landscapes with traditional turf-oriented landscapes. The water savings were estimated at 42 percent for the front yards of homes using water-conserving landscapes.

In September 1990, Assembly Bill 325 was passed and added Article 10.8 to Chapter 3, Division 1 of Title 7 of

the Government Code. This legislation required the Department to develop a model landscape ordinance. The ordinance used a water budget approach relying on ET₀ data in the required landscape design. The water budget specified an average landscape coefficient of 0.5, divided by a minimum irrigation efficiency of 0.625, to yield an *ET Adjustment Factor* of 0.8. This factor was then used to adjust the average annual ET₀.

Water conservation will undoubtedly continue to play a significant role in balancing California's water supply with urban, agricultural, and environmental water needs. Proven conservation measures will be implemented by more agencies and new measures will gain acceptance. Current measures for landscape conservation have yet to affect statewide landscape water use noticeably. However, BMPs and ordinances for landscape water use have only been adopted since 1991 and 1992. Agencies will need to manage water in new ways and prepare differently for shortages as water use continues to become more efficient.

Lake Perris, in Riverside County, receives water at mile 450 of the Governor Edmund G. Brown California Aqueduct. The cost of water varies with the distance it is transported from source to user.

Over 10,000 public and private water agencies provide water to communities throughout California. These include municipal water companies, independent special districts, and private purveyors regulated by the California Public Utilities Commission. More than 300 of these agencies serve 3,000 or more connections.

Most of these local agencies are directly involved in the retail sales of water to urban users. However, some only wholesale water to other agencies. In addition to local agencies, the U.S. Bureau of Reclamation operates the Central Valley Project (and other federal projects) and the California Department of Water Resources operates the State Water Project. Water supplied from these projects is sold to local retail and wholesale agencies throughout the State. Sometimes water supplies will pass through one or more wholesalers and a retailer before reaching the final users.

Factors Affecting Water Prices

Many factors influence the retail water prices levied by urban water agencies. Some of these are discussed below.

Source

Water prices depend greatly on the costs of obtaining the water supplies. For example, the cost of diverting water from a river and using it on adjoining land can be less than \$2 per acre-foot. In contrast, the cost of sea water desalination is about \$2,000 per acre-foot.

Transportation

Another significant factor is the distance water must be transported from the source to the ultimate place of use. For example, the State Water Project delivers supplies to users in northern, central, and southern California. Water delivered to Southern California must travel through hundreds of miles of aqueducts and be pumped over a mountain range before reaching the final destination. Like a train ticket, SWP transportation costs increase

with the distance traveled, although power revenues may offset part of these costs.

Costs

Generally, water provided for urban needs costs more than that for agriculture. This is because urban supply systems are more complex. To meet domestic water quality standards, urban systems often involve costly local facilities for system regulation, treatment plants, distribution systems, water meters, and system operation, including meter reading and customer billing. In addition, some water prices include costs for waste water treatment. However, agricultural water prices are at the *farm head gate*, or edge of property, and seldom need treatment. Farmers incur additional costs to distribute water supplies throughout their farms.

Water treatment costs can be a significant component of total water costs to urban water agencies. These agencies must adhere to drinking water standards set by the federal government (the Federal Safe Drinking Water Act of 1974, amended in 1986) and by the State government (the Safe Drinking Water Act of 1976, amended in 1989). Amendments to these acts may significantly increase future water treatment costs because of more stringent water quality standards.

Weather

During years of normal or above-normal precipitation, most agencies' supplies are adequate to meet current demands. But drought years can significantly disrupt the availability of water and can affect agency water rates. For example, during the 1987-92 drought, many water purveyors adopted more conservation-oriented water rates. Several even implemented drought penalty rates designed to drastically reduce water use. These policies resulted in a substantial reduction in average water use. However, an unwanted consequence of reduced water use for metered systems was reduced revenues to the agencies, which still must pay their fixed costs plus the costs of expanded conservation programs. Hence, to remain solvent many water agencies had to increase retail water prices several times.

Water Pricing Policies

The policies adopted by the various water agencies will also significantly affect the retail prices charged to consumers. Some agencies use water prices to fully recover the costs of acquiring and delivering supplies, whereas others use a combination of water prices and local property taxes. Policies concerning the use of meters and rate structure are also important. Although most urban retail agencies in the State use meters to monitor customer use and to levy charges, some (mainly in the Central Valley) do not. Typically, the costs to consumers of using unmetered supplies are less than if those same supplies were metered. With metered water, customers pay for all water used. In contrast, unmetered water customers pay a flat rate regardless of quantities.

Where supplies are metered, rate structure becomes important. For example, most agencies have switched from declining block rates (where unit water costs decreased with increasing usage) to either constant or increasing block rates. These rates encourage water conservation.

Urban Retail Water Prices

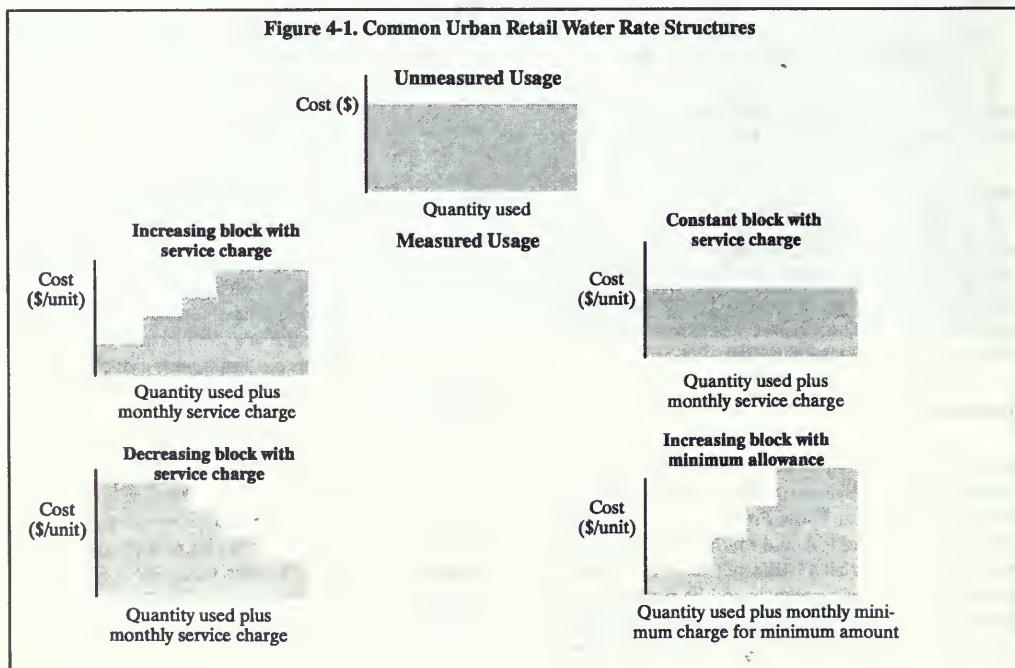

Urban retail water prices are very complex because of the large number of agencies and different pricing policies in use throughout the State. In addition to differences among the water agencies, each agency is likely to have different pricing policies for different customer classes, such as residential, commercial, and industrial.

Rate Structure

The most common rate structures include a monthly service charge plus either an increasing, constant, or decreasing per unit block rate. With an increasing block rate, increasing rates are charged for higher water consumption. With a constant block rate, a constant rate is charged for all levels of consumption. In contrast, a declining block rate structure has decreasing rates for higher water consumption. However, most cities have switched away from declining block rates to encourage water conservation.

An agency's pricing policies are reflected in its rate structures. Figure 4-1 illustrates some of the common urban rate structures.

Figure 4-1. Common Urban Retail Water Rate Structures

A variation of these rate structures is the use of a minimum monthly charge instead of a service charge. With a minimum monthly charge, a minimum amount of water use is allowed at a certain rate. However, consumption over the minimum amount is then subject to a per unit charge.

Another type of rate structure is a flat rate, where the customer pays a set amount each month regardless of the amount of water consumed. Flat rates are still found in the Central Valley where some cities do not have residential water meters.

Because of the factors discussed at the beginning of this chapter, there is tremendous variation in water costs throughout the State. To illustrate this, Figure 4-2 compares 1990-91 single family retail water costs (on a cost per acre-foot basis) for selected California cities. **Because of the prolonged and severe drought, some of these water costs may be higher than what would have been expected for a non-drought year.** This is particularly true for Santa Barbara, which enacted strict drought penalty rates to encourage additional water conservation. However,

the underlying relationships of water costs in the State shown by the figure are still valid—water costs generally increase from north to south and water costs are usually less in the Central Valley compared to coastal locations.

The Department recently compiled 1990-91 water use and cost information for many water agencies throughout the State. Based on this information, the Department estimated average monthly water costs (i.e., water bills) to the different customer categories for these agencies. This information is presented in Appendix F: Urban Retail Water Costs.

Urban Wholesale Water Prices

Numerous agencies within the State wholesale water supplies to other agencies, which ultimately deliver these supplies for urban or agricultural uses. The two largest agencies are the U.S. Bureau of Reclamation and the California Department of Water Resources. Two of the larger local wholesaling agencies are the Metropolitan Water District of Southern California and the San Francisco Water Department. Each agency has its own pricing policies.

Figure 4-2. Single Family Retail Water Costs from Selected California Cities (1990-91)
(in dollars per acre-foot)

U.S. Bureau of Reclamation

USBR operates the Central Valley Project, which delivers about 7 million acre-feet per year to contractors in the Valley. These supplies are used primarily for agriculture, although there are some municipal and industrial deliveries.

Municipal and industrial contractors are charged cost-of-service rates. Preliminary 1993 M&I cost-of-service rates range from about \$4.30 to over \$140 per acre-foot.

USBR pricing policies are undergoing significant revisions as the result of the Central Valley Project Improvement Act of 1992. Several provisions of this act will potentially influence USBR water prices, including requirements for pricing reform to encourage conservation, metering water use, and fish and wildlife restoration activities.

California Department of Water Resources

DWR operates the State Water Project, which currently wholesales water to 29 contractors located in the following service areas: Feather River, North Bay, South Bay, San Joaquin Valley, Central Coastal, and Southern California. The primary components of SWP water costs include a Delta water charge and a transportation charge. The Delta water charge is paid by all contractors and recovers capital and operation, maintenance, and replacement costs, plus interest, associated with the SWP conservation (storage) facilities. The transportation charge is paid by contractors served by transportation facilities. This charge recovers capital and OM&R costs, plus interest.

In 1992, average water costs to the SWP service areas were as follows:

Service Area	Cost/AF
Feather River	\$ 20
North Bay	\$ 166
South Bay	\$ 80
San Joaquin Valley	\$ 49
Central Coastal	\$ 626
Southern California	\$ 243

The Metropolitan Water District of Southern California

MWD is composed of 27 member agencies; 14 are also wholesale agencies that serve their own member agencies (such as the San Diego County Water Authority). In 1990,

the total population of MWD member agencies was about 14.9 million people. MWD deliveries to member agencies in 1990 totaled about 2.5 MAF. MWD imports its supplies from the SWP and Colorado River. In addition, MWD works with member agencies to improve conjunctive use of local ground water supplies.

MWD's water pricing structure for member agencies includes five service classes: non-interruptible (primarily M&I uses), interruptible (primarily agricultural and ground water recharge uses), emergency, seasonal storage, and reclaimed. In addition, within each of these classes (except reclaimed), a distinction is made whether supplies are treated or untreated. The 1993 rates for these classes were as follows:

Class	Cost/AF
Non-interruptible	
Untreated	\$318
Treated	\$385
Emergency	
Untreated	\$954
Treated	\$1,021
Seasonal Storage	
Untreated	\$208
Treated	\$253
Reclaimed	\$113

San Francisco Water Department

SFWD provides both wholesale and retail water supplies, with wholesale users representing about 60 percent of the city's deliveries. Wholesale supplies are delivered to 33 cities and water districts. In 1990, SFWD served a total of about 2.6 million people. SFWD obtains its supplies from the Tuolumne River in the Sierra Nevada (Hetch-Hetchy system) plus local reservoirs in the Bay Area. In 1990, a connection was installed to allow transfers from the SWP to the Hetch-Hetchy system.

As of July 1, 1992, SFWD was charging its wholesale customers about \$379/AF plus a service charge based on the customer's meter size. This service charge ranges from under \$10 per month to over \$5,000, depending on the size and type of meter.

Property Taxes and Other Assessments

Although most urban water customers receive bills for the amounts of water delivered, these bills often do not reflect the total cost of water supplies to the users. Many

local water agencies also collect property tax revenues and other assessments. For example, during the 1989-90 fiscal year, the MWD collected about \$90 million in ad-valorem property taxes, annexation charges, and allocated county-wide taxes on utilities. These revenues represented about 16 percent of the combined MWD water sales and tax levy revenues for that fiscal year.

Another example of the use of assessments is the Kern County Water Agency. KCWA has contracts with its member agencies to recover the costs of imported SWP supplies. Most of these costs are recovered through payments from those agencies receiving the supplies. In turn, these agencies obtain revenues from user charges and assessments levied directly on the water user. However, KCWA also uses an ad-valorem *zone-of-benefit* assessment to recover some of the cost for agricultural SWP supplies. The premise is that other individuals besides the water users benefit from the project. Delivery of SWP supplies improves ground water levels and benefits the local economy. Others besides the direct water user should therefore share in the project costs.

KCWA's SWP water used for urban needs is not supported by zone-of-benefit assessments, except KCWA levies a special zone-of-benefit to pay for SWP water used by its Improvement District No. 4. (ID No. 4 includes most of the urban Bakersfield area and is KCWA's largest user of urban SWP water supplies.) This special zone-of-benefit is in lieu of a contract for water service, as with KCWA's other member agencies.

Urban Ground Water Costs

Local water agencies provide supplies to most residential and commercial customers in the State. Within the industrial sector, small manufacturing firms also obtain sup-

plies mainly from water agencies. However, many large water-intensive manufacturing firms (such as refineries and chemical manufacturers) have developed their own ground water supplies.

Ground water costs vary widely throughout the State. Many factors influence these costs, including depth to ground water, electricity rates, pump efficiencies, and treatment requirements. Typically ground water costs are less than the costs of agency-supplied surface water. Table 4-1 presents ranges of urban ground water costs for the hydrologic regions. These costs include capital, operations (including pumping energy costs), maintenance, replacement, and treatment costs. These costs were obtained from a survey of water agencies.

Table 4-1. 1992 Urban Ground Water Costs by Hydrologic Region	
Hydrologic Region	Ground Water Costs (\$/acre-foot)*
North Coast	75-85
San Francisco	85-330
Central Coast	200-300
South Coast	45-190
Sacramento River	50-80
San Joaquin River	70-270
Tulare Lake	80-175
North Lahontan	120-190
South Lahontan	85-90
Colorado River	115-275
*These costs are higher than pumping raw water for agricultural use because capital, operation, maintenance, replacement, and treatment costs are greater. Source: Bulletin 160-93, Table 6-6	

Forecasts for future water demands are difficult because they will be affected by where future generations live, the jobs they hold, and how they use and conserve California's water resources.

Chapter 5. Forecasting Water Demand in California

Urban water use forecasting is an essential component of the development of the California Water Plan. Reliable estimates of future water use are needed by all water purveyors to plan for an adequate future water supply and to evaluate the effects of water conservation programs on applied water demand. This chapter provides an overview of commonly used forecasting techniques and introduces the Water Savings Simulation Program, a new direction for Department forecasting efforts. Details on the development and preliminary testing of the WSSP are contained in Appendix G.

Methods of Forecasting Water Demand

Water use forecasting methods relate expected changes in one or more explanatory variables to future water use. The various methods differ in the number of explanatory variables and the presumed effect of these variables on current and future water use. Early forecasting methods relied solely on service area population as the explanatory variable, assuming a direct relationship between population growth and applied water demand. However, as discussed in Chapter 3, water demand may grow at a different rate than population, according to the various factors that affect water use.

Water use forecasting techniques can be classified as one of four general methods (Table 5-1). There is a wide range in the sophistication and data requirements among these methods. In general, the more complicated are the most data intensive. Following is an overview of each method beginning with the least complex.

Time Series Analysis

Water use forecasting using time series analysis is based on the assumption that past trends in water use will continue into the future. Implicit in this assumption is that relationships between water use and the explanatory variables will either remain unchanged or continue to change as they have in the past. This method is perhaps the most basic forecasting technique and probably the most limited in accuracy for long-term forecasting.

Time series analysis is simple to perform and can be used alone or in conjunction with another method. Urban applied water demand is forecast by simple extrapolation of a predefined relationship. The relationship can be determined by expert judgement, graphical extension of historical data, or mathematically.

Time series techniques are the least data intensive of the four general methods. Records of past water use are the only input necessary. Time series analysis provides acceptable results over the short term, especially when there is an abundant water supply and steady socioeconomic growth.

If historical population data are available, the time series method can be used to project water use through time on a unit basis (e.g., per capita or per connection). The resulting water unit use coefficients are used in combination with estimates of population growth rates to forecast future water use. This combination method has been used by the Department to forecast statewide urban water demand.

Water Use Coefficient Methods

Unit water use coefficients, such as per capita water use, are valuable for studying water consumption trends and for forecasting future consumption. The initial values of the coefficients are derived by dividing total water consumption for a category of water use by the number of units, or end-users, within the category. Water use is forecasted by multiplying the water use coefficient by the projected number of end-users at the forecast year. The water use coefficient can be assumed fixed through time or

Table 5-1. Urban Water Use Forecasting Methods

Method	Basis of Water Use Forecast
Time series	Extension of historical water use trends
Water use coefficient	Historical water use data; historical and predicted tally of end users
Regression	Historical water use data; historical and predicted values of one or more explanatory variables
Component	Historical water use data; historical and predicted values of one or more explanatory variables for each defined component of urban water use

projected by extrapolation to change according to past water use patterns.

End-users are specified for each category of water use primarily on the basis of past correlation with water consumption. The end-user is typically defined as a person, an employee, or a service connection. The per capita water use approach is the most commonly used water use coefficient method, where the end-user is the service area resident and water use is expressed on a per person (i.e., per capita) basis.

The water use coefficient method can be used to forecast overall water use or specific categories of water use. Geographic variations in explanatory variables can be accounted for by performing forecasts for each subarea of the water service area. The single explanatory variable in this method is the number of end-users.

The water use coefficient method is widely considered to be the most simple and inexpensive method to forecast water use with some accuracy. The only data requirements are historical and projected unit population, and historical water use. However, this method in basic form fails to take into account many important variables that influence water use, such as changes in the ratio of single to multifamily dwellings, climate, commercial and industrial growth, income, and price of water. Therefore, forecast accuracy may decrease sharply in the mid- to long-term period.

Regression Analysis

Regression methods employ statistical techniques such as least squares regression to model water use as the function of one or more explanatory variables. The choice of variables is based on past correlation with water use. Forecasts of water use are calculated based on projected future values of the explanatory variables combined according to the regression model. This method can be applied to overall water use or to individual end-user sectors. Geographic variations in explanatory variables can be accounted for by performing separate forecasts for each subarea of the water service area.

Regression methods can be separated into *requirements models* and *demand models*. Requirements models do not include the price of water as an explanatory variable, with the implicit assumption that water use is a basic requirement unaffected by changes in economic conditions. The

time extrapolation and water use coefficient methods discussed previously are also requirements models.

Demand, or econometric models, include the cost of water to the user, usually accompanied by a measure of personal income. Although the price of urban water currently explains relatively little of the variance in water use, it could become more important if water prices increase significantly. Further, price is usually the only variable that can be controlled by the water supplier and is increasingly used to manage demand when water is in short supply. However, under California law, water agencies cannot make excessive revenues, which limits the prices that can be charged. Continually expanding population combined with new environmental regulations are increasing the probability of water shortages in California. Therefore, understanding the interactions between price and water use will become essential for forecasting urban water consumption.

Component Water Use Forecasts

The determinants of water use vary according to water use sector. Chapter 2 discusses how the Department classifies various types of water use. Proper classification is important because variables that best explain water use in one sector may be less effective or inappropriate for explaining use in other sectors. Further, models specified for a particular geographic area may not hold in areas of differing climate and socioeconomic conditions.

To address this problem, water resource planners are developing component methods of forecasting water use. In this design, overall water use is separated into components according to geography, water use category, or season of year. The nature and number of components is determined according to the purpose of the forecast and the availability of data. Water use is then forecasted separately for each of the components based on the explanatory variables best related to each component. For example, residential water use is strongly correlated with housing type, lot size, and climate, whereas commercial water use is better related to the number of commercial employees. Spatial variation in water use can be accounted for by defining geographic components according to socioeconomic and climatic variables. Seasonality of use (discussed in Chapter 3) can be accounted for by conducting separate forecasts for summer and winter. The forecast of overall water use is obtained by summing the individual component forecasts.

The Water Savings Simulation Program

The Water Savings Simulation Program is a component forecasting system designed to account for the impacts of demand management techniques such as the best management practices. WSSP was developed by the Department of Economics at University of California, Los Angeles, under contract to the Department of Water Resources. A preliminary version of the program was released in April 1993.

The WSSP system uses simulation techniques to produce multiple estimates of water consumption for each year of the forecast period. Each estimate is based on randomly selected values of each input variable. The resulting forecasts are presented as a series of point estimates with confidence intervals to indicate the actual range of probable forecast values. The confidence intervals widen through time (Figure 5-1) to convey the increasing level of uncertainty as forecasts are carried into the future.

The Department is conducting a pilot study involving 10 water service areas, one in each hydrologic region of California (Table 5-2). The results of the study will be

used to assess the accuracy of the forecasts and to define potential enhancements to the program. The final version of WSSP will be used to forecast urban applied water demand for each hydrologic region of California. More detail on the WSSP and its application are discussed in Appendix G.

Table 5-2. Water Service Areas of WSSP Pilot Study by Hydrologic Region

Hydrologic Region	Water Service Area
North Coast	Eureka, City of
San Francisco Bay	East Bay Municipal Utility District
Central Coast	Santa Barbara, City of

WSSP Forecast of Urban Water Use

Sources of Data

There is no requirement in California for water purveyors to report water production and related delivery data to a central agency. Therefore, gathering such information to make estimates of water usage is an involved process drawing on various sources. Many agencies, including local suppliers and statewide and regional planners, are interested in water use data. In preparing bulletins and reports, the Department collects and verifies numerous individual data sets from the local water purveyors.

In a 1993 report, *Drinking Water Into the 21st Century*, the Department of Health Services reports that drinking water is supplied to California residents through a myriad of governmental agencies, cities, districts, private utilities, mutual water companies, private businesses, and individually-owned wells. DHS estimates that there are over 10,000 water suppliers ranging in size from 5 to over 700,000 service connections, subject to some level of drinking water standards enforcement, serving about 29 million consumers. In addition, over 300,000 residents obtain their water from private individual wells. Systems with fewer than five service connections are not subject to enforcement of standards.

Appendix A of Bulletin 166-4 includes an 11-year history of applied water data from 298 retail urban water suppliers. Applied water demand is not adjusted for system losses and other depletions discussed elsewhere in the bulletin. Most of this information is submitted voluntarily to the Department annually on forms provided through DHS and State Controller's office surveys (Figure 6-1). The information includes the amount of water delivered into the system (produced water), deliveries to the users, the number of active accounts, the extent of customer metering, deliveries for various uses (residential, commercial, industrial, and governmental), the area served,

and other factors. Some suppliers did not submit complete information.

Both publicly-owned and privately-owned systems provide water to urban retail customers in California. Cities, water districts, irrigation districts, and other special districts and political subdivisions of the State are publicly owned. Investor-owned water companies (regulated by the California Public Utilities Commission), mutual water associations, and other non-public suppliers are privately-owned.

Data Collection and Geographic Uniformity of Data Coverage

Because of the great number of water purveyors throughout the State, it is virtually impossible to locate and gather data from each and every water system. Although record keeping has greatly improved among the water agencies over the past decade, water use records are still not universally available. True statistical sampling requires that each entity selected must contribute data and that no part of the data sample be withheld. In practice, that level of response is not possible. Instead, all data are gathered and reported as available to maximize coverage of the population served.

Where possible, the larger agencies areas were selected to obtain a higher coverage of the State's population, and generally to secure more complete records. However, with the widespread use of computers today, even the smaller and more remote agencies have the capability of maintaining quality records. Table 6-1 summarizes 1980 and 1990 population distribution by hydrologic region and the percentages of population reported by the data in Appendix A. Table A-1 compares 1980 and 1990 population by county and the percentages reported by the data in Appendix A.

CLEAN WATER CLIENT SERVICES

FISCAL YEAR: 1993
 COUNTY OF:

Figure 6-1. Urban Water Utility Statistics (DWR reporting form)

Figure 6-1 (continued). Urban Water Utility Statistics (DWR reporting form)

INSTRUCTIONS FOR COMPLETING URBAN WATER UTILITY STATISTICS FORM

1. CLASSIFICATION AND NUMBER OF ACCOUNTS

Show the number of **FLAT-RATE** and metered accounts in each classification of use. Separate by location **INSIDE**, or **OUTSIDE** of the corporate city limits. Do not include inactive accounts, hydrants or fire protection connections. The number of accounts should be the average for the calendar year. **IRRIGATION** deliveries should be divided into **AGRICULTURAL CROP** and **LANDSCAPE** (parks, golf courses, etc.) subcategories. Do not include accounts of other agencies that you may serve.

2. RESIDENTIAL

Show the number of single-family dwellings and the number of all other dwelling **UNITS** (not structures) that you serve. (This housing data may be available at the Planning Commission Office, or at other agencies of the city or county governments, and in the Census of Housing).

3. ESTIMATED RESIDENT POPULATION SERVED — (Your Service Area Only)

Base permanent population estimates on most recent (1990) Census count; or special census that may have been taken recently. Unless the city limits are the same as the water agency service area, individual census tracts constituting the water service area can be totaled. A persons-per-connection factor computed from the latest census year can be used for estimating population served. **DO NOT INCLUDE** tourist, "weekend" population, or population of other cities to which water is sold through another agency.

4. MONTHLY WATER PRODUCTION — (Your Service Area Only)

Indicate measured quantities of water produced and introduced into the system for each month of the **CALENDAR YEAR**. **Do not include** amounts of water sold to other water utilities. Also show the amount of **RECLAIMED** water acquired for resale. Do not include **RECLAIMED** water that has been discharged, percolated or evaporated.

5. SOURCES OF WATER

Indicate the percentage of your water supply that is **SELF-PRODUCED** and that which is **PURCHASED**. Then divide each category to show the percentage of water from **WELLS** and/or from **SURFACE SUPPLIES**.

6. METERED DELIVERIES — (Your Service Area Only)

Show monthly delivered amounts for each class of use whether revenue producing or not. Under the category **METERED DELIVERIES-RESIDENTIAL**, show the amount of water delivered to apartments separately from the amount of water delivered to single-family dwellings. The category of **COMMERCIAL** may include water for construction, line flushing or other uses in addition to business uses. The category of **INDUSTRIAL** for this report, means industries that manufacture a product (S.I.C. Major Groups 20 - 39). **GOVERNMENTAL** should include any water delivered to a public facility (that is schools, public buildings, military installations, etc.). **IRRIGATION** deliveries should be divided into **AGRICULTURAL CROP** and **LANDSCAPE** subcategories. Include **RECLAIMED** water delivered for these purposes.

7. DELIVERIES TO OTHER AGENCIES

Indicate whether, or not, you deliver water to another water agency. If affirmative, provide that agency's name and amount in million gallons. **Do not** include this amount in 4, 5 and 6 (other side).

8. UNUSUAL EVENT

Occasionally, an abrupt change occurs in data. Often the change is easily explained by some major change in the system, system operation or service area. If this may have occurred during the past year, please identify the event.

NOTE: If you have already completed a similar form issued by the Office of the State Controller, please disregard this form.

IMPORTANT: Please return this colored original form.

Source: Department of Finance, Report I 80-90, Intercensal Estimates of the Population of California: State and Counties 1980-1990, June 1991.

Population Served

The boundaries of water purveyor service areas seldom correspond to those of overlying census tracts, census designated places, city limits, or other boundaries for which populations can be determined. The calculation of per capita water use estimates depends on reliable estimates of the *permanent* resident population of a water service area. *Transient* populations (e.g., recreational and tourists) are counted in the population of their permanent residence, even though their water use affects the values of the areas they visit.

There are various methods to estimate service area populations. Wherever possible, official census or annual Department of Finance update estimates are applied. For a given water service area, an estimate of persons per connection can be multiplied by the known number of service connections. However, the number of persons per connection varies within and between communities due to housing configurations (single-family or multi-family, ranchettes, etc.) and the mix of land uses (residential, commercial, industrial, etc.). In some cases, the estimated persons per connection of an overlying agency (county or water district) can be assumed as a reasonable estimate for an underlying service area or a similar community.

Appendix A identifies the city served by each retail water supplier. For this bulletin, *city* is used in a broad sense, from the geographic extent of a concentration of resi-

dences and work places, to a metropolitan area, central city, and suburbs. A city in this sense is a named community and may be incorporated or not. An urban water supplier may serve all or part of city, plus customers beyond its central boundaries, and/or all or parts of more than one city.

In Appendix A tables, 1980 and 1990 *city census population* refers to the official population of the closest overlying census place. This is for comparison with the water supplier's estimated service area population. In some cases, census information is used with persons per connection information to estimate service area population.

Verifying Data

The Department receives most data from agencies on the form shown in Figure 6-1. Some agencies are unable to complete the form as requested for various reasons. In some cases, their accounting system does not aggregate the requested data, or totalizing meters have not been installed on intake lines to the system. Many systems in the Central Valley and some remote areas do not meter some or all residential customers. Some agencies are unable to identify total services or to accurately count the individuals within their service area.

A large part of the data analysis process involves checking data for accuracy. Each water agency has a unique water system, accounting method, and data collection technique. Therefore, each response must be examined to ensure that

the correct units of measure were used and that questions on the response form were interpreted properly.

Extraordinary impacts on per capita water use may need special attention. For example, the tourist, non-resident population of Palm Springs and vicinity raises water use to more than 800 gallons per capita daily. High unit rates of water use occur in the Lake Tahoe basin because of high year-round tourism. Exceptionally high industrial water use may have a similar effect. The lumber and paper manufacturing industries in the North Coast Region require considerably more water than other urban users. If this amount of water were assigned to the resident population, the rate would be several thousand gpcd. The amount of water delivered to very high-water-using industries is treated as a separate demand and not included with the normal urban requirement.

Uses of the Data

As reported by the local water purveyors and verified to the extent possible by the Department, Appendix A constitutes a unique set of water information. Analyses of these data are presented in the Bulletin 166 and Bulletin 160 series.

The Department uses per capita water use to identify trends in the data in Appendix A. On a local basis, per capita use is affected by many factors, as discussed above and in Chapter 3, that must be considered when comparing the gpcd of various localities. Summarizing per capita use by hydrologic regions and statewide remains a valid method of estimating water use.

The data in Appendix A have been used in this report as follows:

1. Estimates of unaccounted water were prepared from the data by comparing the difference between water produced and metered deliveries. Unmetered water deliveries may complicate such calculations.
2. The monthly water production data allowed for analysis of seasonal patterns of water use.

3. The average of the 1980-87 data was used to establish the 1990 *normalized* use that was not affected by rationing or conservation methods used only during the drought.
4. The normalized per capita water uses are multiplied by population and adjusted for conservation to make projections.
5. Where data were available on the water use by sector, they were used to calculate percentage water by sector for each hydrologic region.
6. The lowest water use in the winter months over the 1980-87 period was considered an approximation of the interior *baseline* use.

While the data in Appendix A have been useful in the Department's statewide and regional water use estimates and forecasts, it needs strengthening to better estimate the factors affecting current use and for future projections.

Urban water use data are also important for studies to:

1. Identify developing water supply shortages
2. Evaluate the availability of water for local use, export to other areas of need, or both
3. Determine the ability of users to pay for additional water supplies
4. Analyze ground water extraction rates
5. Quantify water rights
6. Determine the quantity and nature of water use (including the timing of applications and the routing of water) to optimize State and federal reservoir operations
7. Assist evaluation of the impact of proposed water management actions and facilities on specific areas.

Questions concerning the data may be directed to the Water Use Unit in the appropriate Department of Water Resources District Office (Figure 6-2).

1/ Number of services

3/ gpcd - gallons per capita daily

2/ Excludes services for agriculture, fire hydrants,
fire protection, and other agencies.

4/ afpca - acre-feet per capita annually

Appendix B

Glossary

Account: The fiscal status of one customer. For billing purposes, one account may include several apartment complex structures, and more than one connection, but under a single ownership.

Acre-foot (AF): a quantity or volume of water covering one acre to a depth of one foot; equal to 43,560 cubic feet or 325,851 gallons.

Applied Water Demand: the quantity of water delivered to the intake to a city's water system or factory, the farm headgate, or a marsh or other wetland, either directly or by incidental drainage flows (this is water for wildlife areas). For instream use, it is the portion of the stream flow dedicated to instream use or reserved under the federal or State Wild and Scenic Rivers acts.

Best Management Practice (BMP): an urban water conservation measure that the California Urban Water Conservation Council agrees to implement among signatory agencies.

Commercial Water Use: A broad class of urban water use including water deliveries to non-governmental office buildings, restaurants, retail services, and other business establishments and private golf courses and recreational facilities including transient lodging.

Connection: Customer service line through which water is delivered to a structure or other urban user (e.g., park, cemetery, golf course) from a water service agency.

Delivered Water: A part of total **Applied Water Demand** which is received by the end user.

Demand Hardening: A concept used to describe how rationing programs during periods of water shortage become less effective and/or more costly over time as established conservation practices such as BMPs reduce the potential for demand reduction.

Depletion: The water consumed within a service area or no longer available as a source of supply. For urban water use, it is evapotranspiration of applied water (ETAW) (water applied to landscaping or home gardens), sewage effluent that flows to a salt sink, and incidental evapotranspiration (ET) losses. For agriculture and wetlands, it is ETAW (and ET of flooded wetlands) plus irrecoverable losses. For instream use, it is the amount of dedicated flow that proceeds to a salt sink.

Detailed Analysis Unit (DAU): The smallest study area used by Department of Water Resources analyzing water demand and supply, generally defined by hydrologic features or boundaries of organized water service agencies. In the major agricultural areas, a DAU typically includes 100,000 to 300,000 acres.

Distribution Uniformity: The ratio of the average low-quarter depth of irrigation to the average depth of irrigation, for the entire farm field, expressed as a percentage.

Effluent: Waste water or other liquid, partially or completely treated or in its natural state, flowing from a treatment plant.

Effective Precipitation: That portion of precipitation that contributes to satisfying the evapotranspiration and/or leaching requirement of a crop, expressed as a depth in inches or feet. It includes the evapotranspiration provided by precipitation during the growing season or that which is carried over into the following growing season as stored soil moisture.

Evapotranspiration (ET): The quantity of water transpired (given off), retained in plant tissues, and evaporated from plant tissues and surrounding soil surfaces. Quantitatively, it is expressed in terms of depth of water per unit area during a specified period of time. As used in this report, evapotranspiration is synonymous with consumptive use.

Evapotranspiration of Applied Water (ETAW): The portion of the total evapotranspiration which is provided by irrigation.

Explanatory Variable: An independent variable (e.g., price, income, population) found through statistical analysis to be useful for explaining variation in a dependent variable (e.g., water consumption).

Flat-rate (unmetered) water deliveries: Unmeasured water delivered to residences, business establishments, and other urban water customers.

Governmental Water Use: A broad class of urban water use including water deliveries to all public facilities including military, educational, civic, publicly owned recreational facilities, and office buildings.

Gray Water: Waste water from a household or small commercial establishment. Gray water does not include water from a toilet, kitchen sink, dishwasher, or water used for washing diapers.

Gross Water Use: The total water produced and introduced into the system of a water service agency, as opposed to **Delivered Water** that includes losses due to line leakage, undocumented water use, back flushing of filters and lines, defective meters, and other diverted uses.

Hydrologic Region: A study area, consisting of one or more Planning Subareas.

Industrial Water Use: Intake water use applied for all manufacturing and other industrial plant uses as defined in the Standard Industrial Classification Manual.

Institutional Water Use: Water supplied to buildings housing organizations that are important in the life of a community or society, especially those dedicated to public service, as a university or place of confinement such as a mental or penal institution. Such water is variously classified as commercial or governmental. The Department of Water Resources classifies institutional water use as governmental.

Irrigation Efficiency: The efficiency of water application and use. Computed by dividing the evapotranspiration of applied water by the applied water and converting the result to a percentage.

Isohyet: A line drawn on a map connecting points receiving equal rainfall.

Net Water Demand: The amount of water needed in a water service area to meet all requirements. It is the sum of evapotranspiration of applied water (ETAW) in an area, the irrecoverable losses from the distribution system, and the outflow leaving the service area.

Normalized Data: Estimated values over time resulting from smoothing the graph of actual data points to minimize skewing. For example, the graph of per capita water use between 1980 and 1990 (Figure 2-2, Trends in Urban Per Capita Water Use) plots the statewide average of 183 gpcd in 1982, whereas a smoothed trend line passing through 1982 would show a normalized statewide value of nearly 200 gpcd.

Per-Capita Water Use: The water produced by or introduced into the system of a water supplier divided by the total residential population; normally expressed in gallons per-capita-per-day (gpcd).

Planning Subarea (PSA): An intermediate size study area consisting of one or more Detailed Analysis Unit(s).

Population: A water agency service area population includes permanent residents living within the service area. This excludes transient visitors, such as campers and vacationers.

Probabilistic: Involving a random variable; involving chance or probability; stochastic.

Produced Water: Water developed by a water supplier either from ground water or stream diversion, or purchased water; each source of which is introduced into the water supplier's water system.

Reclaimed Waste Water: Waste water that becomes suitable for a specific beneficial use as a result of treatment. See also **Waste Water**.

Reference Crop Evapotranspiration (ET₀): The ET rate of healthy grass, completely covering the ground to a uniform height of 3 to 6 inches, and having an adequate supply of water and extensive fetch. ET₀ is estimated by using the University of California modified Penman equation developed for use in the California Irrigation Management Information System.

Residential Water Use: One of the four major classes of urban water use, and includes water service to single family and usually multiple-family dwelling structures and manufactured homes occupied by full time residents. This excludes hotel, motel, transient and recreational visitor water use, which are grouped in the broad **Commercial Water Use** category. See also **Standard Industrial Classification**.

Return Flow: The portion of withdrawn water not consumed by evapotranspiration or system losses which returns to its source or to another body of water.

Reuse: The additional use of water that has previously met an end use.

Salt Sink: A body of water too salty for most freshwater uses, generally the ocean or an inland basin with salty surface and/or ground water.

Self-produced Water: A water supply developed and used by an individual or entity. Also called "self-supplied."

Service Area: The geographical land area served by a distribution system of a water agency.

Standard Industrial Classification (SIC), defines the following categories:

Industrial, or Manufacturing, Division D, Major Group 20 to 39, includes establishments engaged in the mechanical or chemical transformation of materials or substances into new products. Industrial water use means intake water use applied to all manufacturing and plant uses, including cooling, processing, and sanitary.

Commercial includes all other establishments (Divisions C through I, excluding Divisions A (Agriculture), B (Mining), and J (Public administration)).

Governmental, or Institutional (Division J) includes the executive, legislative, judicial administrative and regulatory activities of federal, state, local, international governments, and includes schools and military activities.

Transpiration: The process in which plant tissues give off water vapor to the atmosphere as an essential physiological process.

Type of Water Use: The four generally recognized types of urban water use: residential, commercial, industrial, and governmental. Also referred to as Sectors of Urban Water Use, or Classes of Water Use.

Unaccounted Water: The difference between the measured amount of water produced and introduced into the system, and the measured amount delivered to customers. Unaccounted water may be "authorized" or "unauthorized" losses. Authorized uses include fire-fighting, main and sewer flushing, street cleaning, and public uses such as irrigation for parks and golf courses, schools and cemeteries (some agencies measure these uses). Unauthorized uses may include distribution system leaks, metering errors, theft, and inaccurate system control.

Urban Applied Water Demand: The quantity of water delivered to the intake to a community water system or factory.

Urban Water Use: The use of water for urban purposes, including, but not limited to residential, commercial, industrial, and governmental classes. The term is applied in the sense that it is a type of use rather than a place of use; i.e., although most urban use occurs within a city or town, it also occurs outside of city boundaries, adjoining cities, and in rural areas.

Waste Water: The water remaining after use, liquid waste, or drainage from a community, industry, or institution.

Water Agency (or supplier, or purveyor): An entity (publicly or privately owned) that develops or purchases a supply of water for distribution and delivery to customers within its service area. A wholesale agency delivers water to other water suppliers for their customers.

Water Audit: A process of accounting for an agency's water from the source of supply, through the distribution system, to delivery.

Water Demand: The quantity of water required to support a given level and kind of land use.

Water Demand Schedule: A time distribution of the demand for prescribed quantities of water for specified purposes. It is usually a monthly tabulation of the total quantity of water that a particular water user intends to use during a specified year.

Water Meter: A device for measuring the amount of water delivered into a water distribution system, or to residences and business establishments.

Water Quality: Used to describe the chemical, physical, biological, and bacteriological characteristics of water usually in regard to its suitability for a particular purpose.

Water Reclamation: The planned reuse of waste water for specific beneficial purposes.

Water Requirement: The quantity of water required for a specified use under a predetermined or prescribed situation.

(Water) Withdrawals: A quantity of water produced or developed from surface and ground water sources. In this Bulletin, water withdrawn for retail or wholesale delivery to urban customers.

Weighted Mean: Averaged quantities expressed as sets of numbers to take into account numerically their weight (relative importance) to the total. When weights are all equal, the weighted mean reduces to that of the ordinary (arithmetic) mean.

Appendix D

Water Use and Depletions

Appendix D.

Water Use and Depletions

Chapter 2 discussed population growth and its relationship to per capita water use. Population density is another factor influencing per capita water use. As population per acre increases, per capita landscape area tends to decrease. Table D-1 shows changes in population density by county between 1980 and 1990. The historical urban water use trends shown in Table 2-1 indicate a recent leveling off of per capita water use in most areas of California, possibly due in part to higher population densities and water conservation efforts.

Chapter 1 introduced the terms *net water use* and *depletion*, represented graphically in Figure D-1. The interaction of net water use and depletion varies geographically. For example, along the coast, depletions are nearly equal to net water use since wastewater is discharged into the ocean and is lost or *depleted* from the fresh water system. Inland, less water is depleted because it is reused to recharge ground water or adds to instream flow available for reuse downstream.

Table D-1. Comparison of Population Densities of California Counties, 1980 to 1990

Precipitation and Urban Landscaping

Appendix E. Precipitation and Urban Landscaping

Variance in per capita water use is affected by a number of factors, as discussed in Chapter 3. Figure E-1 shows daily per capita water use of 20 communities relative to precipitation (see also Figure 3-1). Figure E-2 shows per capita use relative to July temperatures.

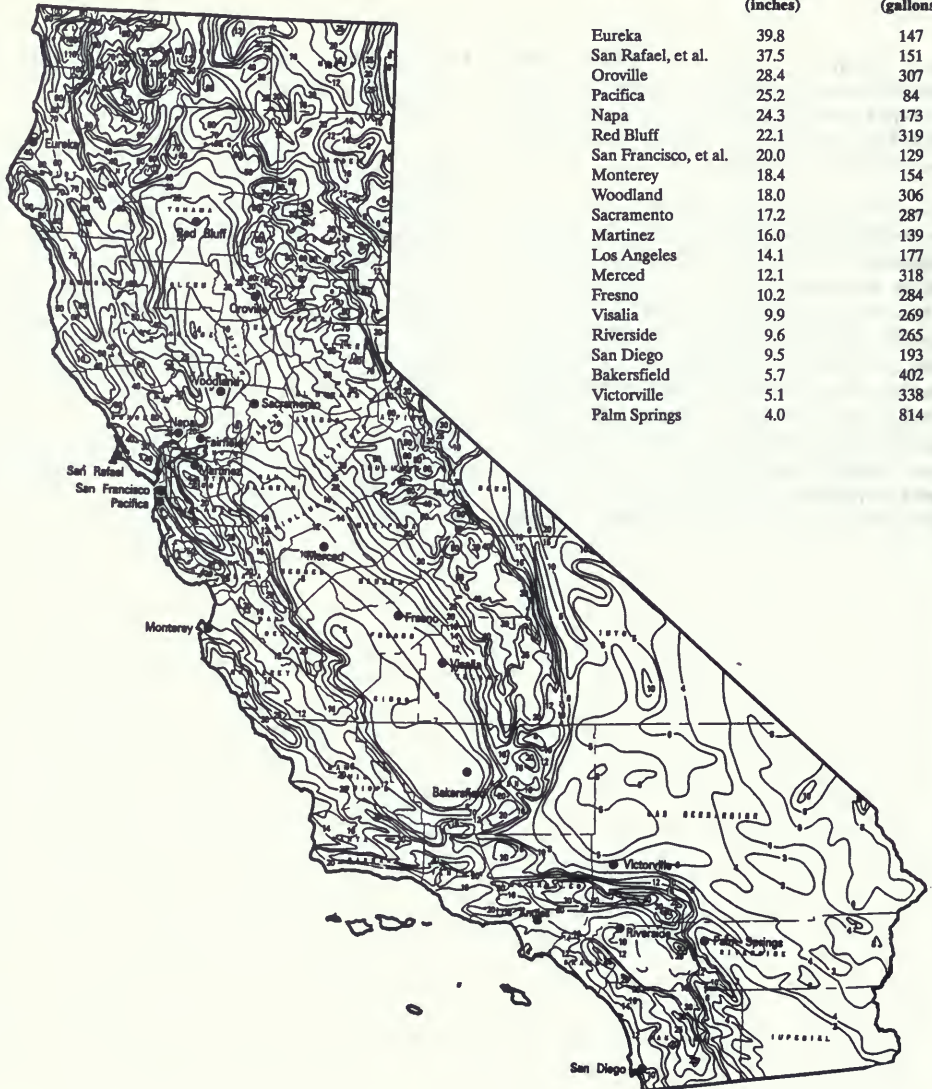

The concept of *effective precipitation* is related to soil moisture deficits (See definition in Appendix B). The Department used the concept of effective precipitation in estimates of vegetative water use in Bulletin 113-3 (1974). More recently, a study of effective precipitation on bare soil in the Central Valley developed a relationship between rainfall and soil moisture changes during the winter months as is shown in Figure E-3 (DWR, February 1989). The relationship illustrates that small amounts of rainfall (less than 1 inch per month) are ineffective and rainfall that is effective is never equal to the measured precipitation. The time when rainfall exceeds evaporative demand occurs during November through

February in most of California (in some desert areas this never occurs). Most plants extract the stored soil moisture in the spring and early summer.

The concepts of effective precipitation and soil-moisture deficit have been used effectively in agriculture but are more difficult to apply to urban landscaping. Irrigation management on a farm is optimized because the fields are normally large, planted to one variety of crop, and evenly spaced in rows. A similar situation exists in landscapes only on large playing fields. While individual homeowners cannot be expected to apply such concepts, urban water managers can use them to analyze and project monthly and yearly demands.

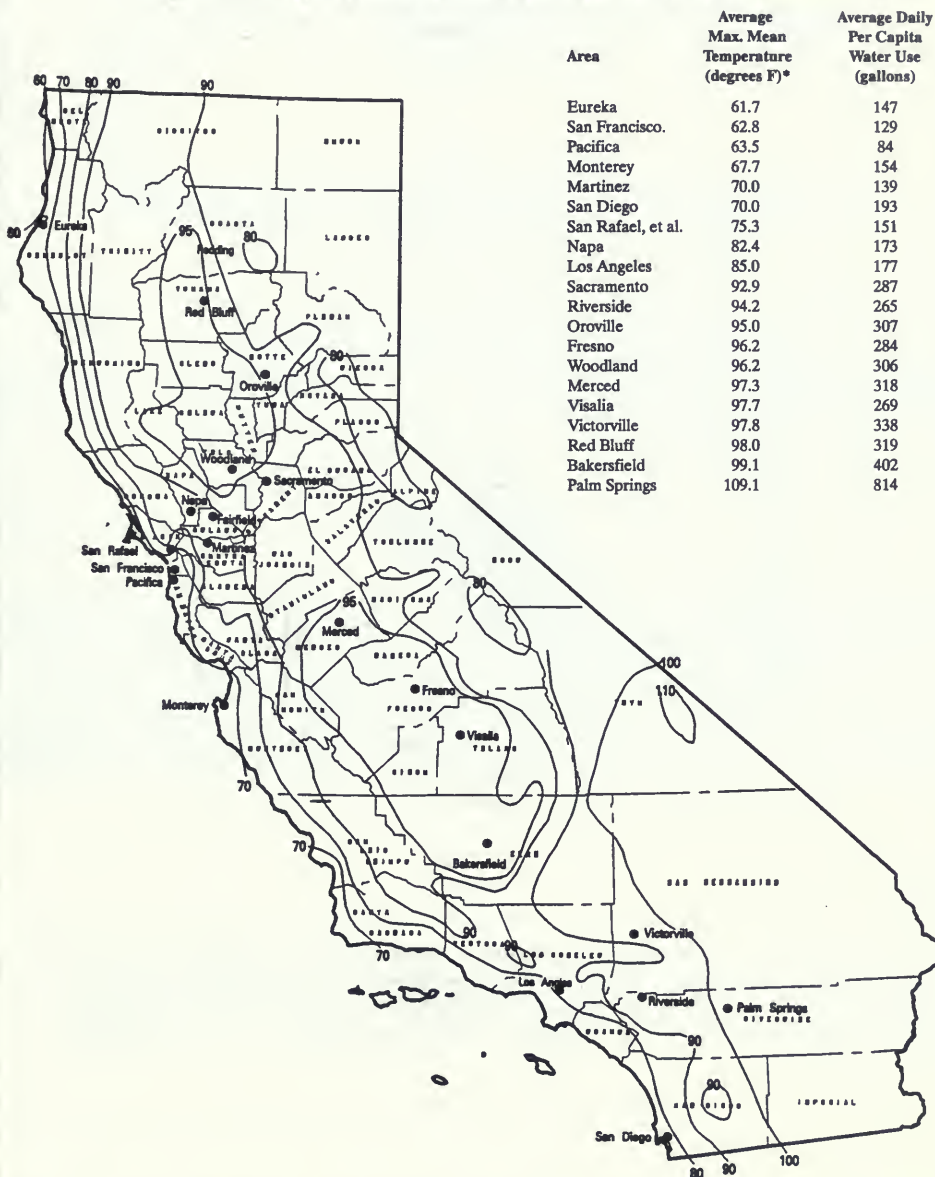

Tables E-1 and E-2 show some results of the application of the Department Agricultural Mobile Lab Program irrigation system evaluation techniques to urban landscape. See also Chapter 3.

Figure E-1. Annual Precipitation and Per Capita Water Use

*Source: DWR Bulletin 113-3 based on 1969 U.S. Geological Survey map

Figure E-2. Average Maximum July Temperatures and Per Capita Water Use

*Source: National Climatic Center, Ashville, NC 28801, as shown in DWR California Temperature Data Maps, January 27, 1982.

Figure E-3. Normal Monthly Evaporation and Rainfall for Two Precipitation Zones in the Central Valley

Evaporation

The period of greatest rainfall coincides with the period of lowest evaporative demand. Figure E-3 shows normal monthly rainfall and corresponding evaporation rates for two precipitation zones in the Central Valley. The shaded areas represent rainfall that exceeds evaporation. Although precipitation varies widely, evaporation rates are relatively constant throughout the Valley. Therefore, rainfall in excess of evaporation varies with the total amount of precipitation.

Table E-2. Estimated Values for Species, Density, and Microclimate Factors Used to Determine the Landscape Coefficient (K_L) for Selected Vegetation Types¹									
Vegetation Type	Species Factor (K_s)			Density Factor (K_d)			Microclimate Factor (K_{mc})		
	high	avg	low	high	avg	low	high	avg	low
Trees ²	0.9	0.5	0.2	1.3	1.0	0.5	1.4	1.0	0.5
Shrubs	0.7	0.5	0.2	1.1	1.0	0.5	1.3	1.0	0.5
Groundcovers	0.7	0.5	0.2	1.1	1.0	0.5	1.2	1.0	0.5
Mixed ³ trees, shrubs, groundcovers	0.9	0.5	0.2	1.3	1.1	0.6	1.4	1.0	0.5
Turfgrass ⁴	0.8	0.7	0.6	1.0	1.0	0.6	1.2	1.0	0.8
¹ Species factor values for trees are estimates based on research from agricultural tree crops while groundcover estimates are based on preliminary research findings in California.									
² The tree, shrub, and groundcover categories listed are for landscapes composed solely or predominantly of one of these vegetation types.									
³ Mixed plantings are composed of two or all three vegetation types (i.e., where a single vegetation type does not predominate).									
⁴ A low K_s value (0.6) should be assigned to warm-season turf and a high value (0.8) to cool-season turf. Turfgrass values are included to provide irrigation managers with a complete table of coefficients used to estimate landscape water use.									
Note: It is assumed that there is no bare soil surface within the landscape planting. Otherwise K_d should be increased 10 to 20 percent, especially for trees and shrubs due to soil surface evaporation.

Appendix F

Urban Retail Water Costs

Appendix F.

Urban Retail Water Costs

This appendix presents results of a 1990-91 survey of retail water costs for many agencies located throughout the State. Because of drought conditions at the time, many of these costs are higher than what would have been expected during a non-drought year.

Computing total water costs requires two types of information for each customer class: water use and rate structure. For single family residential customers, DWR compiled actual 1990-91 water use and rate structure information. The monthly service charge for a single family residential customer is based on either a 5/8 inch or 3/4 inch size meter, depending on the agency's rate structure.

Table F-1 summarizes single family residential seasonal monthly use and water cost information for 59 selected agencies. For each agency, the table shows the county and hydrologic region (See Figure 2-1 in Chapter 2), average summer water use per customer, average winter use, typical monthly summer and winter bills, and an equivalent cost per acre-foot estimate (which includes service and commodity charges). Also shown is the effective date of rates used in the computation.

Table F-1 shows that some of the higher bills are found in agencies located along the coast, such as Marin Municipal Water District, the City of Santa Barbara, Goleta Water District, and Monterey Peninsula Water Management District. Some of the lower bills are found in agencies located in the Central Valley, such as the cities of Sacramento and Fresno. Figure 4-2 in Chapter 4 compares residential retail water costs for eight selected cities.

Table F-2 gives average monthly residential water use and cost information of an additional 26 water agencies. For these agencies, seasonal water use information was not available. Hence, the table presents only average monthly water use and cost information.

Table F-3 and Table F-4 summarize average monthly water use and cost information for commercial and industrial customers for selected cities. In contrast to single family residential customers, which as a group tend to have similar water uses, it is difficult to define a *typical* commercial or industrial customer. This is particularly true for the industrial sector, which includes bakeries as well as oil refineries. Table F-3 and Table F-4 indicate that some of the higher commercial and industrial water costs are also found along the coast. Some of the lower costs are found in the Central Valley.

Figure F-1 illustrates how total water use costs are charged to single family residential users. The graphs show a comparison of total water use costs of selected agencies based on differing rate structures (excluding monthly service charges). Since rate strategies differ by agency, water costs for some accelerate faster for higher usage in some agencies. For example, the total water use costs for Los Angeles (LADWP) increase at a constant rate for additional water use; this represents a constant block structure.¹ But the use costs for Pasadena switch to a higher rate after 15 ccf reflecting an increasing block structure. In addition, both cities have different water costs between summer and winter use, reflecting seasonal rate structures.

The remaining cities shown in Figure F-1 do not have seasonal rate structures. Water use costs for the City of Long Beach switch to a higher rate after 5 ccf, but the use costs for the City of Burbank increase at a constant rate. Water use costs for Santa Barbara switch after 4, 12, and 32 ccf due to the increasing block rate structure. In contrast, Goleta's water rate starts at a higher level than Santa Barbara but increases at a constant rate. For the City of San Jose, the water use costs switch to a higher rate after 4 ccf, but the additional water costs for the City of San Francisco increase at a constant rate.

Figure F-2 shows how retail commercial and industrial water costs (for a hypothetical monthly use of 100 ccf) are broken into the monthly service charge and the actual use charge. For example, the City of Sacramento does not levy a charge based on water use. The monthly water cost is based on the fixed service charge alone. In comparison, the City of Santa Barbara collects a greater proportion of the water bill through water use charges.

Since many complex factors influence water prices, definitive conclusions concerning water uses and water costs among cities cannot be derived solely from these tables and graphs.

¹ Since completion of DWR's survey, LADWP adopted an increasing block structure.

Appendix G

Water Savings Simulation Program

Appendix G. Water Savings Simulation Program

Forecasts of urban water use are often based on *point estimates* of one or more random variables. Each point estimate approximates the central tendency of a probability distribution. However, many forecasting methods fail to acknowledge the random nature of the model inputs and cannot account for the compounding of errors in the combination of point estimates. The resultant forecasts are misleadingly precise, implying a much greater degree of accuracy than the uncertain nature of the input data actually allows. To remedy this problem, the Water Savings Simulations Program (WSSP) system employs simulation techniques to make random draws of each uncertain quantity used in the calculation of water use and savings. The resulting forecasts are presented in the form of point estimates *and* confidence intervals to convey the uncertainty inherent in the forecasting process.

Basic Methodology

The WSSP system uses simulation techniques to produce multiple estimates of future water consumption for each year of the forecast period. Each estimate is based on randomly selected values from user-defined distributions of each of the uncertain ingredients in the forecast and savings formulas. The selected values are combined according to the forecasting model to produce a single estimate of water use for each forecast year. The process is repeated until, at present, 500 simulations are generated and saved for each year of the forecast period. Program output can be displayed either in tabular form or as line plots of various percentiles of the distributions of the 500 water use estimates (i.e., confidence intervals). Figure G-1 illustrates how the confidence intervals increase in width the further one forecasts into the future, indicating the range of possible values for each year of the forecast.

The WSSP system estimates future values of water use according to the following general relationship:

$$U_{t,w} = f(H, N, I, V, P, E, C)$$

where

- $U_{t,w}$ = average water use in year t , and water use category w , a function (f) of random variables
- H = number and type of housing units
- N = number of persons per household
- I = income
- V = building vintage
- P = price of water
- E = employment
- C = conservation

First, water use is forecasted under existing laws and current level of conservation (baseline use). Then, an estimate is made of the expected water savings due to implementation of increasingly intensive conservation efforts such as the Best Management Practices. The expected savings are subtracted from the baseline to estimate future water use.

The relationships between water consumption and the various explanatory variables were estimated on the basis of Department studies, water agency data, and literature review. Subsets of these explanatory variables are combined to forecast water use in each defined water use category. The separate estimates are combined by summation to give overall water use.

Figure G-1. Presentation of WSSP Forecast Results

WSSP Forecast of Urban Water Use

Water Savings Simulation Program forecast results in the form of the 5th, 25th, 50th, 75th, and 95th percentiles of the distribution of simulation estimates. The 50th percentile plot represents the most likely value for each year of the forecast period under the given assumptions.

Baseline Water Consumption

The WSSP system forecasts baseline water consumption using a variation of the water use coefficient method, modified to account for the effects of certain explanatory variables. Water consumption for each category is estimated by multiplying the appropriate water use coefficient by the number of end users in the category. The end user is specified according to the user category. A resident of the water service area is the end user for the residential water use categories, while an employee in the commercial, industrial, or governmental sectors is specified for the non-residential categories.

Water use coefficients are modeled to change to reflect the influence of various explanatory variables on water consumption. Residential water use coefficients vary according to the number of persons per household, conservation efforts, personal income, and water price. Commercial and industrial coefficients are influenced by conservation and water price. The governmental coefficients are affected by conservation efforts.

Conservation Savings

The WSSP system evaluates water savings due to the set of water conservation efforts known collectively as the BMPs. Forecasts of water savings are specified by BMP and water use category. The potential reduction in consumption due to each BMP is estimated according to the following relationship:

$$S_{c,w,t} = U_{w,t} * R_{c,w} * P_{c,w,t}$$

where

$S_{c,w,t}$ = water savings resulting from the implementation of conservation measure c , in water use category w , at time t , expressed in gallons per day

$U_{w,t}$ = base year water use in water use category w at time t , expressed in gallons per capita daily

$R_{c,w}$ = reduction in water consumption resulting from the implementation of conservation measure c , in water use category w , expressed as a proportion of base year water use.

$P_{c,w,t}$ = population affected by conservation measure c , in water use category w , at time t

The BMPs were drafted by the California Urban Water Conservation Council to speed implementation of urban water conservation measures and to estimate the market penetration and consumption reduction factors for certain BMPs. At present, these estimates have been adopted as the default basis of water savings calculations by WSSP. As with the other input parameters to the WSSP system, these assumptions can be modified by the user as appropriate. Forecasts of water savings can be prepared for each BMP, or aggregated to estimate savings by water use category or overall.

Data Requirements

The WSSP system forecasts water use as a function of a defined set of explanatory variables. The current and future values of the explanatory variables are supplied by the user. Three general kinds of data are required: the actual values of base year water and socioeconomic variables, the projected values of the socioeconomic explanatory variables for the forecast year, and savings assumptions for each demand management technique. Alternate futures can be considered by preparing separate sets of input data to represent differing scenarios of socioeconomic growth and conservation effectiveness. Data specific to each water service area are required for population, household size, housing units, building vintage, employment, income, water consumption, and price. Table G-1 lists the menu of input variables to be specified for each water service area. Basic data were obtained from a number of sources, including federal, State, regional, and local agencies. Table G-2 lists the major sources of input data to the WSSP system.

Table G-1. WSSP Water Use and Socioeconomic Input Variables	
Water Use	
Water use by sector, base year	
Single family	
Multi family	
Commercial

Pilot Forecasting Project

DWR is currently using WSSP in a pilot study to forecast urban water consumption in several areas of the State. Ten water service areas were selected for study, one in each hydrologic region of California (Table G-3). The purpose of the pilot study is to evaluate the accuracy of the WSSP forecasting system, define potential enhancements to the program, and test the feasibility of using WSSP to forecast urban water use statewide.

Table G-3. Water Service Areas of WSSP Pilot Study by Hydrologic Region	
Hydrologic Region	Water Service Area
North Coast	Eureka, City of
San Francisco Bay	East Bay Municipal Utility District
Central Coast	Santa Barbara, City of
South Coast	San Diego County
Sacramento River	Sacramento, City of
San Joaquin River	Stockton, City of
Tulare Lake	Fresno, City of
North Lahontan	Susanville, City of
South Lahontan	Victorville, City of
Colorado River	El Centro, City of

Preliminary Forecast of Urban Water Use in San Diego County

The WSSP system was used to forecast urban water consumption within DAU 120, which comprises the urbanized coastal plains and inland valleys of San Diego County and includes about 97 percent of the county population.

Figure G-2 shows the forecast of urban applied water demand for DAU 120, in thousand acre-feet per year. This forecast considers the effect of existing laws and level of conservation (including the 1992 plumbing code revision) and the BMPs on urban water demand. The output is displayed as line plots of various percentiles of the distribution of 500 water use estimates for each year of the forecast period. The best point estimate of water use for a given year is shown in the form of the 50th percentile of the distribution. Urban applied water use is shown to increase through the period, mainly due to increased population.

Figure G-3 illustrates the forecasts of urban applied water demand for DAU 120 by end-user category. The growth paths are depicted by the 50th percentile of the simulation results for each category (single family residential, multi-family residential, commercial, industrial, and governmental/other). According to the forecast, the single-family residential category will remain the largest of these five components of overall water use, and will grow at the fastest rate in the long term. Commercial water use is also expected to grow quickly relative to the other categories, while industrial water use shows little growth over the forecast period.

Figure G-2. Forecast of Urban Applied Water Demand
DAU 120 Forecast of Urban Water Demand

Forecast of urban applied water demand in DAU 120 under full implementation of BMPs; simulation results in the form of the 5th, 25th, 50th, 75th, and 95th percentiles of the distribution of 500 simulation estimates.

Figure G-3. Forecast of Urban Water Consumption by End-User Category
DAU 120 Forecast of Urban Water Demand By Sector

Forecast of water use by end-user sector (single family residential, multifamily residential, commercial, industrial, and governmental/other) shown as median values of 500 simulation estimates

For any planning period, the rate of growth in urban applied water demand will differ from the rate of population growth. The result is variation in per capita water use over the period. Figure G-4 shows the forecast of per capita water use for DAU 120. According to the forecast, per capita use can be expected to decline until about 2010, then level off. The initial decline shows the affect on water demand of many variables, including the 1992 plumbing code revision, implementation of the BMPs, and an increase in the proportion of multi-family to single family housing units. The relatively level long-term trend reflects an expected reduction in household size in DAU 120 and full implementation of the BMPs.

Figure G-5 illustrates the expected annual water savings over the forecast period due to the BMPs. These totals do not include the reduction in demand owing to changes in laws or regulations such as the 1992 plumbing code revision. Annual savings are shown to grow quickly over the near term as efforts to implement the BMPs are intensified. The growth in annual savings levels off in the long term as full implementation of the BMPs is approached.

The forecast of water savings varies by end-user category, as shown in Figure G-6. Annual savings in the residential categories are expected to grow in the short term, but decrease over time. The expected annual savings in the non-residential categories ranges from nearly constant over the forecast period in the governmental/other category to steadily increasing in the industrial and commercial categories. The disparity in the growth paths of residential and non-residential water savings is based on the definition of savings. As mentioned previously, the WSSP does not count demand reduction due to laws or regulations as savings. A large portion of the demand reduction in the residential categories is expected to stem from the 1992 plumbing code revision, whereas reductions in the non-residential categories is assumed to depend primarily on voluntary demand reduction programs and efforts to comply with increasingly strict discharge requirements.

**Figure G-4. Forecast of Per Capita Water Use
DAU 120 Forecast of Per Capita Water Use**

Forecast of per capita water use in DAU 120 under full implementation of BMPs; simulation results in the form of the 5th, 25th, 50th, 75th, and 95th percentiles of the distribution of 500 simulation estimates.

Figure G-5. Forecast of Water Savings Due to BMPs
DAU 120 Forecast of Water Savings Due to BMPs

Forecast of total water savings due to BMPs in DAU 120 under full implementation of BMPs; simulation results in the form of the 5th, 25th, 50th, 75th, and 95th percentiles of the distribution of 500 simulation estimates.

Figure G-6. Forecast of Water Savings Due to BMPs by User Sector
DAU 120 Forecast of Water Savings Due to BMPs By Sector

Forecast of water savings due to BMPs by end-user sector (single family residential, multifamily residential, commercial, industrial, and governmental/other) shown as median values of 500 simulation estimates

Application of WSSP

The Department of Water Resources is currently working to complete preliminary forecasts for the remaining water service areas in the pilot study (Table G-3). Upon completion and validation of the pilot study forecasts, the WSSP will be modified to forecast water use within larger geographic areas such as detailed analysis units and planning subareas. The results will be used to forecast urban applied water demand by hydrologic region and statewide in future updates to the *California Water Plan*.
